one of the other forms of statement, and by his complaint, he invalidates all claims to property rights in any of the means which are made use of by the physician. He might as well claim ownership in the tools of the carpenter who has built a coal shed for him, and the Long Catlin, and tenaculum of the surgeon who has performed a surgical operation on him. As said before, the choice of ways and means lies wholly with the physician, and the patient cares not whether the doctor gives him medicine from his own dispensary, or gives him a written order for some druggist to prepare something to order, according to the terms of that order.

The prescription as written, is simply that order, and in the majority of cases the selection of the druggist to carry out its provisions is left to the patient. The written prescription is the intermediary between the doctor and the druggist, and the patient is simply nothing more nor less than a messenger boy who delivers the intermediary.

When the terms of the written prescription are complied with, and the finished medicine is delivered to the patient, either in person or by proxy, the prescription dies the death and takes its place with the things of the past. Its terms are founded on the present—it deals with the present wholly, and except accidentally, it cannot apply to anything of the future; hence, it cannot be renewed except on the direction of the writer, if he should find that the accident has occurred.

I think it may be considered as proved that at no time has the patient any property rights in either the piece of paper or the formula written upon it, as he has paid for neither, but that he has paid for an intangible thing—a benefit to be received. The patient, therefore, cannot "own the prescription."

The written prescription being in the nature of a communication from one person to another, must be the property of the one communicated to, just as an ordinary letter or order; and the subject of the communication has no bearing whatever upon this fact, but the fact that he owns the communication, in no way authorizes that owner to deviate from the matters communicated. As that matter is simply an instruction to do certain things for the benefit of a certain person, who is the one who delivers the communication, the recipient has no warrant for doing those things for anyone else, and for the reason previously given, more than once, or at any future time. There is no need of dwelling on this point, for medical literature teems with protests against it.

Does the physician own the prescription?

The prescription consists of two things. First, the directions for preparation and use, and secondly, the tangible piece of paper upon which the directions are inscribed.

In the event that the doctor has devised a peculiar combination of drugs, and is in that sense an inventor, he most undoubtedly does own the only thing which gives the written prescription any value whatever; and if
he has written the name of a single thing only, the same holds good, for he has established a connection between that thing and the patient, and that is one of the steps he takes towards carrying out his part of the contract, which in no way involves a connection between that thing and any other person.

So far as the mere piece of paper, aside from its value as containing some of the results of the doctor's skill and knowledge is concerned, it is a mere record of things ordered to be done by one person, and done by another. The conclusion hardly needs stating. That piece of paper belongs to the person executing the order; but only as voucher for his authority for doing certain things named on the piece of paper. As the paper and the writing and its meaning cannot be separated, and as the writer in no way parts with his property rights by the mere description of them on the paper, and still has his property stored away in duplicate in his brain, the rights of both parties are served by the retention of the piece of paper by him who carries out its instructions, and far more effectually for the writer, than for the dispenser of the prescription, as the former has a record that he gave certain orders, but the latter may require a portion of the dispensed medicine, and the services of an expert analyst to show that he obeyed the order.

I think it is sufficiently plain that the ownership of the written prescription rests neither with the physician who writes it, nor with the patient who receives it, and that this position is proved by the construction of the original contract by the man who has received no benefits; but there is another phase.

The patient is cured. What then?

The little piece of paper with its unintelligible scrawls is at once invested with value as "My property," I bought it, and it's mine.

The average citizen under such circumstances realizes the fact that the doctor knows his business, or at least has made a good guess. He says: "I had an awful catarrh and this prescription cured me all right. It's a good thing," and he reaches out for it. He claims ownership of the written prescription. In plain words, he steals one of the doctor's tools, and only that, because the others are locked up. He follows the rule of some so-called business men: "Get all you can, whether it belongs to you or not."

If the patient does not own a prescription which is without value, he does not own one which has value, for value has no connection whatever with ownership.

To sum up.

The written prescription is a communication to any druggist to whom it may be presented. Therefore, it cannot be the property of the one for whom it is written, or of the one who presents it to the druggist.

In the absence of special instructions, a prescription may be filled but once, as it is presumably designed to meet present conditions and no
other; and as it is written from the standpoint of a single individual, it may not be filled for more than that one.

As a medical means, the prescription is solely the property of the physician, who devises it and expresses it in language.

As the intermediary between the doctor and the druggist, it is simply a written communication and follows the law of all communications. It therefore remains in the possession of the recipient. This fact is enforced by the fact that after the instructions of the communication are complied with, as a medical means, the life of the prescription ceases and it is reduced to a simple communication.

The conclusion of the whole matter is that after a prescription is once filled it no longer can be considered as an authority and takes the rank of a simple communication, being reduced to a simple record, which should be filled by the one who carried out the instructions contained in the communication.

This conclusion is borne out by the various laws with regard to the dispensing of certain poisons, notably cocaine, etc., and the specification of these certain things is due to the general recognition by the public of the danger of their indiscriminate use. When the time comes when the public realizes the danger in the indiscriminate refilling of prescriptions, laws will be passed by all States prohibiting:

The refilling of any prescription for any but the one for whom it was written.

The refilling of a prescription for any one without the special order of the writer.

The giving of a copy of any prescription, and requiring the keeping of all prescriptions filled as a matter of record.

Such laws necessarily deny the right of ownership to the patient and the doctor as well as to the dispenser, but they vest the dispenser with the rights of a custodian, and sooner or later to this complexion will we come and the moss grown question will be decided for good.

ON TEACHING BACTERIOLOGY IN COLLEGES OF PHARMACY.

BY ALBERT SCHNEIDER.

It may be assumed that it is not necessary to argue that the subject of bacteriology should be taught in every reputable college of pharmacy. We shall therefore confine ourselves to a discussion as to the manner in which this most interesting branch of science should be presented to the students taking the regular course in colleges of pharmacy.

When some twelve or fourteen years ago, instruction in pharmaceutical bacteriology was offered, for the first time, in two or three colleges in the United States, it was made an optional course and the students of pharmacy essayed to take a certain amount of laboratory work with the students of medicine. This method was soon abandoned, for it was only too
evident that medical bacteriology was not suited to the needs of pharmacy. Bacteriology as an optional course in colleges of pharmacy is and always has been wholly unsatisfactory, as are all optional courses of instruction, at least when considered as a factor in the regular college curriculum. Optional courses for special students in the higher branches of learning are wholly consistent, but there is absolutely no place for an optional course in our colleges of pharmacy. The curriculum of studies must be carefully mapped out and every subject taught should be obligatory. An optional course cannot be a factor in a general educational scheme leading to a degree which is supposed to be granted upon the satisfactory completion of certain uniformly representative courses of instruction. Accordingly pharmaceutical bacteriology should either be included in the regular course of instruction in colleges of pharmacy or it should be excluded.

While this phase of the subject could no doubt be argued and is being argued by some pharmaceutical educators, the writer is fully satisfied that pharmaceutical bacteriology should be made an obligatory course of study in every reputable college of pharmacy in the United States. Some of the more general argumentations as to why and how the subject should be taught have been given elsewhere * and we shall at this time devote ourselves to a more specific setting forth of the way in which the subject should be presented to students of pharmacy.

The course in pharmaceutical bacteriology must be adapted to the other courses of instruction. According to the curriculum of studies in the leading colleges of pharmacy the time which may be allotted to pharmaceutical bacteriology must of necessity be very short. After several years of experimenting the writer has finally arranged the work as follows, having in mind a three years' college course.

During the senior year of the regular two years' course leading to the degree of Graduate in Pharmacy, Ph. G.—or Pharmaceutical Chemist, Ph. C.—a course comprising eighteen to twenty-two hours of lectures (one lecture each week), with class demonstrations and several laboratory periods, is given. This is intended to give the students a general survey of the subject in harmony with the progress recently made in the science of pharmacy, and incidentally, this course serves as a preparation for the work in bacteriology during the third year, now generally designated as the graduate course or graduate year.

The lecture course should cover the following subjects approximately in the order given:

1. General Introduction. Purposes of the course. Relationship of pharmaceutical bacteriology and medical bacteriology, etc.

II. **Historical.** A brief summary of the history of the science of bacteriology from the earliest conceptions regarding "disease effluvias," "spontaneous generation," etc., up to the modern conception of vaccines, disease immunity and antitoxins.

III. **The General Morphology of Microbes.** The structural characteristics of microbes; form types, and the earlier attempts at a classification based upon form; occurrence of cilia; spore formation; etc.

IV. **The Classification of Microbes.** Their position from the evolutionary standpoint; their problematical relationship to the lower groups of fungi; the system of Migula and of other authorities; classifications as to form, as to activities displayed, as to occurrence, etc.

V. **The General Physiology of Microbes.** Relationship of bacterial cell activities to moisture, light, temperature, etc.; substances formed as the result of bacterial activity; ptomaines, leucomaines, enzymes, gases, toxins, etc.; assimilation, growth, etc.; propagation of bacteria; cell division and spore formation; etc.

VI. **The Range and Distribution of Microbes.** General distribution; altitudinal and latitudinal distribution; bacteria of earth, air and water; bacteria in and upon plants and animals.

VII. **Harmful Microbes.** Pathogenic bacteria, of plants, of animals; objectionable bacteria of soils, of commercial products; etc.

VIII. **Useful Microbes.** Of soils: of plants; of animals; in the dairying industry; retting bacteria; bacteria as pest exterminators; etc.

IX. **Microbic Culture Media.** Bacterial foods in general, liquid and solid: preparation of artificial culture media; use of indicators; sterilization of culture media; etc.

X. **Microbic Cultures.** Purposes of bacterial culturing: pure cultures; isolation of bacteria; estimating the number of bacteria in solids and liquids; etc.

XI. **Staining Microbes.** Staining methods in general; special stains; purposes of staining; cell stains; spore staining; use of mordants; etc.

XII. **Examination of Microbes.** Temporary and permanent mounting; use of oil-immersion lenses; identification of bacteria.

XIII. **Immunity from Disease.** Natural immunity; acquired immunity: race immunity; etc.

XIV. **Phagocytosis.** Phagocytes as the guardians of health; micro- and macro-phages; leucocytosis in wound infection; pus formation; the "laudable pus" of the older surgeons; etc.

XV. **Wright's Opsonic Theory.** Evidence of the existence of opsonins: opsonins in their relationship to leucocytosis; the opsonic index; the treatment of disease based upon the opsonic theory; etc.

XVI. **The Manufacture of Sera.** Antitoxin of diphtheria; other sera.

XVII. **Small-pox Vaccine.** Manufacture of small-pox vaccine; history of vaccination; value of vaccination.
XVIII. Bacterial Vaccines. Manufacture of vaccines; autogenous and heterogenous vaccines; tuberculins; etc.

XIX. Disinfectants and Disinfection. Disinfectants and their use; sick-room disinfection; disinfection of public buildings; etc.

XX. Pasteurization and Sterilization of Liquids and Foods. Pasteurization of milk and other liquids; preservation of foods and food preservatives; etc.

XXI. Fermentation and Fermentation Products.

XXII. Theoretical Bacteriology. Ultra-microorganisms; diseases of which the primary cause is unknown; virulence and potency; etc.

XXIII. Bacteriological Work for Pharmacists. Equipment of a bacteriological laboratory for pharmacists; bacteriological work which may be done by pharmacists, such as making culture-media for physicians; incubating bacterial cultures; sterilization of pharmaceuticals; etc.

The above outline is intended as a suggestion only, indicating the more important bacteriological topics that are to be covered by the lecture course, which is to be supplemented by an occasional oral or written review. Furthermore the various pieces of apparatus and appliances used in bacteriological work are to be exhibited before the entire class and their use fully explained. In addition to the above, some three or four laboratory periods should be devoted to the examination of living bacteria (motile, non-motile, large and small); mounting and staining bacteria; examination of bacterially infected substances; examination of bacterial slides of well-known bacteria; etc.

During the third or graduate year of college instruction, each student is required to devote a portion of every college day to laboratory work, as follows:

I. Preparation of Artificial Culture Media. Making the more common media as Nutrient Bouillon, Nutrient Gelatin, Nutrient Agar, Gelatin-Agar, Sugar-free Bouillon, Glycerin Bouillon and a few others.

II. Preparation of Glassware. Cleaning glassware; plugging test tubes with cotton; filling test tubes with culture media; sterilization of test tubes, Petri dishes, etc.; making tube slants; etc.

III. Preparing Culture Media for the use of Physicians. Sealing tubes, filled with culture medium, hermetically, ready for immediate inoculation; preparation of sterile throat swabs; preparation of special media which may be required by physicians; etc.

IV. Special Work. After the student has familiarized himself with the preparation of culture media and other necessary laboratory details, he is required to make bacterial cultures; isolation cultures; determining the bacterial content of water supply, of sewage, milk, syrups, waters, tinctures, fluidextracts; etc.

Usually the special work is limited to one problem, as a bacteriological examination of galenicals or of syrups, etc., since the time allotted (one
year) does not warrant undertaking more extended lines of research. The special work might also include making blood counts; microscopical examination of sputa, ejecta, urine, bacterially contaminated foods, drugs, animal tissues, etc.

Wherever possible the course in bacteriology should be supplemented by visits to biological laboratories for the manufacture of sera and vaccines. Students should also be assigned special reading. The reports on bacteriological and related subjects issued from time to time by the U. S. Public Health and Marine Hospital Service are of special value. Practical work in the disinfection of closets, large rooms, buildings, sewage, outhouses, etc., should also be done. In fact the pharmacist who has completed the course in bacteriology as above outlined should be fully qualified to actively assist the public health officers whenever the occasion may require.

*California College of Pharmacy, San Francisco.*

**Third Session—Friday Morning, May 6, 1910.**

The third session of the Section on Education and Legislation was held jointly with the National Association of Boards of Pharmacy and the Conference of Pharmaceutical Faculties, and was presided over by Chairman LaWall, of the E. & C. Section, who called the Section to order at 10:30 a.m.

The Chair called attention to a resolution offered by Mr. Asher at the first session, on yesterday morning, in connection with a paper read by Mr. Kebler on "The Need of a Federal Poison Label," in which the writer made the statement that many preparations upon the market at the present time, while they contained poisonous doses of powerful substances, were not required to be labeled "Poison." At the close of the reading of that paper the Section had placed itself on record as favoring the requirement that such a label be placed on remedies of that kind, and Mr. Asher's resolution was:

**Resolved,** That this Association recommend that the Foods and Drugs Act be modified, so that a suitable poison label will be placed on all packages of drugs where twenty times the stated dose of said substance would have toxic action.

The Chair called for action on this resolution.

Mr. Rudder, of Indiana, asked if this included physician's prescriptions, as well as other packages, and Mr. Cliffe responded that, as he understood Mr. Kebler's request, it was to be applied to these preparations, as well as to proprietary articles.

The Chair agreed with this view, but said he simply wanted to give the resolution as offered by the gentleman authorized to prepare it.

Mr. Pritchard said he thought the word "modified" in the resolution
was unfortunate. It was hardly proper to "modify" the law; it should be made stronger than that.

The Chair said he hardly thought the resolution was in line with the object of the session of yesterday, and Mr. Prichard suggested that it was not quite full enough.

Thereupon the Chair said he would entertain a motion that the resolution be redrawn, and that the Chair appoint a committee to do that. Acting upon this suggestion, Mr. Mayo moved that the Chair appoint a committee of three, to put this resolution into such shape as conformed with the understanding had at the last session, and that this committee take action immediately, and report to the Section. This motion was seconded and carried, and the Chair said he would appoint on this committee Mr. Pritchard, Mr. Cliffe and Mr. Rudder.

The Chair stated that, although in the nature of repetition, he wanted to ask Mr. E. F. Cook to devote a few minutes at this point to an explanation of his methods of book-keeping for pharmacists, as set out in his paper presented yesterday, at which time very few members were present, and then the members could examine his illustrative matter at their leisure, after the close of the session.

Mr. Cook presented his subject accordingly, exhibiting and showing the use of various ledgers, forms, etc., used in his course of teaching at the college with which he was connected.

The Chair stated that Mr. Hynson had a matter that he wished to bring up at this time, and he would be given the privilege of the floor for ten minutes to do so.

Mr. Hynson said the matter he wanted to bring before the Section was as to the form in which the text of the National Formulary was gotten up, and he desired to bring out some discussion on that subject, as he thought it would be a matter of interest to the members. In his judgment, it was a matter of urgency, and one requiring a good deal of thought. He referred the members to some three or four typewritten sheets of comparative formulas distributed among them, and first invited attention to the official formula for syrup of bromides, and criticised it in several respects. His first criticism was directed to the reprint of the word "bromide" four times in succession, instead of the ditto ("') mark under the word as it first appeared, as shown in his proposed form on the last half of the sheet. His next criticism was as to "Tincture of Vanilla (U. S. P.)" His objection here was that it was unnecessary to indicate that the product should be U. S. P. or N. F., because that was always implied and understood. This criticism would also apply to the three remaining items of the formula. He also called attention to what he thought was an improvement in the proposed formula, of having two separate columns for the quantities given, in grams and cubic centimeters, respectively, as compared with the method employed in the official formula of placing all in
the same column. He called attention to the form of directions, which he had changed.

The official formula criticised and the substitute proposed here follow:

**SYRUPUS BROMIDORUM.**

_Syrup of Bromides._

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Gm.</th>
<th>Cc.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Potassium bromide</td>
<td>80</td>
<td></td>
</tr>
<tr>
<td>Sodium bromide</td>
<td>80</td>
<td></td>
</tr>
<tr>
<td>Ammonium bromide</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>Calcium bromide</td>
<td>25</td>
<td></td>
</tr>
<tr>
<td>Lithium bromide</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>Tincture of vanilla (U. S. P.)</td>
<td>82</td>
<td></td>
</tr>
<tr>
<td>Compound tincture of cudbear (N. F.)</td>
<td>16</td>
<td></td>
</tr>
<tr>
<td>Compound syrup of sarsaparilla (U. S. P.)</td>
<td>450</td>
<td></td>
</tr>
<tr>
<td>Syrup (U. S. P.), a sufficient quantity to make</td>
<td>1000</td>
<td></td>
</tr>
</tbody>
</table>

Dissolve the bromides in the compound syrup of sarsaparilla and 400 Cc. of syrup; then add the tinctures, and sufficient syrup to make 1000 Cc.

**SYRUPUS BROMIDORUM.**

_Syrup of Bromides._

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Gm.</th>
<th>Cc.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Potassium bromide</td>
<td>80</td>
<td></td>

<td></td>
</tr>
<tr>
<td>Sugar</td>
<td>225</td>
<td></td>
</tr>
<tr>
<td>Water</td>
<td>1000</td>
<td></td>
</tr>
</tbody>
</table>

In a solution of the bromides, in the water, dissolve the sugar; to this add the compound syrup of sarsaparilla, the tinctures and enough syrup to make the whole measure 1000 Cc.

Mr. Hynson's next criticism was as to the formula for aromatic vinegar, and he objected to the use of capital letters in naming the ingredients of the formula, as also the use of both Centigrade and Fahrenheit thermometers, as he thought one was sufficient.

The original and proposed formulas here follow:
ACETUM AROMATICUM.

Aromatic Vinegar.

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oil of Lavender</td>
<td>0.5 Cc.</td>
</tr>
<tr>
<td>Oil of Rosemary</td>
<td>0.5 Cc.</td>
</tr>
<tr>
<td>Oil of Juniper</td>
<td>0.5 Cc.</td>
</tr>
<tr>
<td>Oil of Peppermint</td>
<td>0.5 Cc.</td>
</tr>
<tr>
<td>Oil of Cinnamon</td>
<td>0.5 Cc.</td>
</tr>
<tr>
<td>Oil of Lemon</td>
<td>1 Cc.</td>
</tr>
<tr>
<td>Oil of Cloves</td>
<td>1 Cc.</td>
</tr>
<tr>
<td>Alcohol</td>
<td>175 Cc.</td>
</tr>
<tr>
<td>Acetic Acid (U. S. P.)</td>
<td>175 Cc.</td>
</tr>
<tr>
<td>Water</td>
<td>1000 Cc.</td>
</tr>
</tbody>
</table>

Dissolve the Oils in the Alcohol, add the Acetic Acid, and lastly, enough Water to make 1000 Cc. Warm the turbid mixture, during several hours, at a temperature not exceeding 70° C. (158° F.), taking care that it shall not suffer loss by evaporation. Then set it aside for a few days, occasionally agitating, and filter.

ACETUM AROMATICUM.

Aromatic Vinegar.

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oil of lavender flowers</td>
<td>0.5</td>
</tr>
<tr>
<td>Oil of rosemary</td>
<td>0.5</td>
</tr>
<tr>
<td>Oil of juniper</td>
<td>0.5</td>
</tr>
<tr>
<td>Oil of peppermint</td>
<td>0.5</td>
</tr>
<tr>
<td>Oil of cinnamon</td>
<td>0.5</td>
</tr>
<tr>
<td>Oil of lemon</td>
<td>1.0</td>
</tr>
<tr>
<td>Oil of cloves</td>
<td>1.0</td>
</tr>
<tr>
<td>Alcohol</td>
<td>175.0</td>
</tr>
<tr>
<td>Acetic acid</td>
<td>175.0</td>
</tr>
<tr>
<td>Water</td>
<td>1000.0</td>
</tr>
</tbody>
</table>

Mix the acetic acid with the volatile oils, dissolved in the alcohol, and add enough water to make one liter. Keep this mixture at a temperature between sixty and seventy degrees, centigrade thermometer, several hours, avoiding loss of volume by evaporation. Afterwards, agitate occasionally, for a few days and filter.

Mr. Hynson next took up copaiba mixture. He called attention to the fact that in the National Formulary the general heading "Copaiba Mixtures" was used, and under that the sub-head, "1. Lafayette Mixture," and thought the form of heading given in his proposed formula, where he showed, "Compound Copaiba Mixture (Lafayette's)" was an improvement.

The official and proposed formulas here follow:
CRITICISM OF N. F. FORMULAS.

MISTURÆ COPAIBÆ.

Copaiba Mixtures.

1. Lafayette Mixture.

Copaiba ........................................... 125 Cc.
Spirit of Nitrous Ether (U. S. P.) .................. 125 Cc.
Compound Tincture of Lavender (U. S. P.) .......... 125 Cc.
Solution of Potassium Hydroxide (U. S. P.) ....... 32 Cc.
Syrup (U. S. P.) .................................. 300 Cc.
Mucilage of Acacia (U. S. P.), a sufficient quantity to make.. 1000 Cc.

Mix the Copaiba with the Solution of Potassium Hydroxide and the Spirit of Nitrous Ether. Then add the Compound Tincture of Lavender, and lastly, the Syrup and Mucilage of Acacia. Mix the whole thoroughly by shaking.

MISTURA COPAIBÆ COMPOSITA.

Compound Copaiba Mixture, (Lafayette's).

Cc.

Copaiba ........................................... 125
Spirit of nitrous ether ................................ 125
Compound tincture of lavender ....................... 125
Solution of potassium hydroxide ................... 30
Syrup ............................................. 300
Mucilage of acacia, a sufficient quantity to make.. 1000

Thoroughly mix the copaiba with the solution of potassium hydroxide; to this add sufficient mucilage of acacia, to make 450 Cc., and the syrup. Mix well. Finally add the compound tincture of lavender and the spirit of nitrous ether and carefully mix the combination.

The Chair stated that this matter was open for discussion, but suggested that he thought it was one that should probably be brought to the attention of the Committee on National Formulary for consideration. Mr. Hynson said he had already consulted the Chairman of this committee, and he said he would be glad to have it brought before the Section on Education and Legislation.

Mr. Motter moved that this subject be brought before the Committee on Editing, together with the discussion that might take place.

This motion was duly seconded.

Mr. Taylor said that while he did not know anything about the peculiar hieroglyphics produced here, he did know something about problems of editing, and he could see a great deal of horse-sense in the proposition presented. It was exactly in line with the proposition that had already been brought before the Association, as to the necessity of concerted action along this line, and he thought if the presenter of this paper would briefly draw off the items he had presented, as he had explained them, it would be very helpful to the Committee on Editing.

Mr. Hynson said he would like to call particular attention to the use of
capitals in the text of the National Formulary, and also of the Pharmacopoeia. He said that, to him, had been one of the most disturbing things he had to contend with, when looking at the National Formulary or the Pharmacopoeia, this thing of so many capital letters, as it diverted the attention from the substance of things.

Mr. Payne explained this condition from the fact that these formulas were gotten up by different men, and passed upon by different committees, and it was only natural that there should be some variance in the working and arrangement of the different formulas. Referring to the first formula named by Mr. Hynson, he was free to say he preferred the word "Bromide" written out each time, as given in that formula, rather than the use of the ditto-mark. He thought it would be especially desirable to have the name spelled out, where any matter of this sort came before the court. He thought the section was likely to devote a lot of valuable time to this subject, that might be more profitably used otherwise.

Mr. Apple said he thoroughly agreed with Mr. Hynson as to leaving off the letters "U. S. P." after the name of the ingredient. If the student was not sufficiently conversant with the composition of a drug where it was official, he thought it was certainly a reflection upon the institution that turned him out as a finished scholar; that it was a great reflection on his alma mater if he did not know that tincture of vanilla, for example, was a U. S. P. product, and not an N. F. product. He doubted the advisability of using ditto-marks, however, and preferred that the name of the drug be spelled out, as it was only a question of typesetting, and it made it very clear and left no possible question as to what was meant.

Mr. Good agreed with Mr. Hynson as to the use of ditto-marks and the dropping of capital letters, as he had likewise been annoyed and diverted by the profuse use of capitals.

The Chair stated that if there was no further discussion on this matter, it would be referred to the Editing Committee, to report on at the last session of the Association in general session, to which it was empowered to report.

The motion was so put and carried.

The Chair called on Mr. Pritchard to report on the resolution referred earlier in the session to the committee of which he was chairman, Mr. Pritchard made report as follows:

Resolved, That this Association recommend that the Foods and Drugs Act be amended, so that a suitable poison label be placed upon all packages of proprietary remedies containing toxic drugs, in every case where the bottle, box or container holds a toxic dose of any of its ingredients.

Mr. Emanuel referred to the peculiar fact that in Russia alcohol was labeled "Poison," and when the ignorant peasant saw the skull and crossbones he immediately grabbed for the bottle. He thought this tendency
ought to be avoided, and that the use of the word "poison" should not be cheapened. He would favor the statement that all proprietary medicines containing toxic drugs should bear a statement on the label of the quantity of that medicine which would be fatal to adult human life, without placing a poison label on it.

Mr. Roe, of Indiana, expressed the opinion that the word "suitable," covered the case.

Mr. Pritchard ventured the assertion that no committee could be appointed which could draft a law, or present an amendment to a law, which would cover every idiosyncrasy of every individual.

The Chair agreed with Mr. Roe that the use of the word "suitable"—"suitable poison label"—was broad enough to cover this proposition.

Mr. Apple objected to the idea of "tinkering" with the Food and Drugs Act, and thought if anything was desirable along this line it would be better to secure it by way of an independent act, and not as an amendment to the present act.

Mr. Motter, referring to Mr. Pritchard's statement that it would be impossible to draft a law that would meet with the approval of everybody, everywhere, said that in his opinion, there was too much law. There was too much of a disposition on the part of many people to think, when a thing did not go to suit them, that they must rush off to Congress or their State Legislature and have some law enacted, or some law amended, to accord with their peculiar views. He considered the present National Food and Drugs Act as a fairly good one, and it was still on trial, as it were, and it would very much complicate matters to have it amended. The act was being generally criticised now for its stringency in certain directions. He did not believe the danger arising from the use of these drugs was commensurate with the disadvantage which would follow from making the word "poison" so general in its application to drugs as to cause people to be careless in their use. There were very few proprietary or non-proprietary preparations which were not dispensed in sufficiently large proportions to constitute a poison if the entire package were taken at one time. But, on the other hand, if the use of the word "poison" was made very general, the public would come to disregard it, whereas, as at present understood, it had a clear, definite meaning in the public mind. He did not believe it was desirable to undertake to pass any amendments to the Food and Drugs Act which were not imperatively required, because there was danger of having it injured, instead of improved. As Mr. Bode-mann had said, in a paper read before this Section, it was good policy not to try to improve a law, unless it was reasonably certain that it would not be made worse by the effort.

Mr. Gammon agreed with Mr. Motter that it would be a mistake to tamper with the Food and Drugs Act. He thought there was nothing which cheapened a society or organization as much as too much legislation, and he hoped this resolution would not prevail.
Mr. Cliffe reminded the members that the committee had acted on the positive instruction of the Section to bring in a resolution which met with the views of the Section as expressed in the discussion which had occurred yesterday on this very proposition, and they had attempted to do so. He said if it was the wish of the members not to adopt the resolution, they had a perfect right to do so, and that the committee had no prejudices in the matter.

Mr. Good asked that the resolution be re-read, and this was done by the Chair.

The Chair stated that the effect of this resolution was, that if a package of a proprietary remedy contained enough of a toxic drug to kill a person if the whole package were taken, such package should be labeled with a poison label.

Mr. Payne said while he agreed with the principle of the resolution, and thought it was excellent, yet if an attempt was made to apply it in a legal way it would bring a great many complications.

Mr. Pritchard called attention to a paper read by Mr. Kebler at the Louisville Meeting of the N. A. R. D., in which he spoke of the fact that while all the States were attempting to put a stop to the use of habit-forming drugs by legislative enactment, there were numerous concerns advertising alleged “cures” for such drugs, which examination showed contained large quantities of the very drug they were professing to cure the use of; and that a number of people had found when they resorted to these “cures” that they became worse, instead of better—that they were “actually furnishing the fuel to keep the fire going.” He said that Mr. Kebler’s idea in his paper before the Section on yesterday was to call attention to the fact that these preparations were being distributed all over the United States.

Mr. Mayo said he did not think the remarks of Mr. Pritchard were germane to this particular resolution. He thought the Cuilom Bill or the Foster Bill, so far as the Government was concerned, would cover this question of interstate sale of narcotic and habit-forming drugs more effectively than anything that could be done by this resolution.

Mr. Taylor asked if he was correct in the understanding that Mr. Kebler had discussed this matter as the result of his personal experience. The Chair responded that he was sorry Mr. Kebler was not present to speak for himself, but he did not think his intention was to make the matter quite as broad as it had been made in this resolution; that he thought his purpose was to make it apply more specifically to certain instances which had come under his observation.

Mr. Taylor then proceeded to discuss the situation in New York, and said the present pharmacy law required that all poisons be labeled. He expressed himself as favoring the proposition that proprietary remedies containing poisons should bear a poison label, as well as others. He sug-
gested that the subject might be referred to the Committee on Legislation, and let them thrash it out in detail.

Mr. Engstrom read the section of the Massachusetts law bearing on this subject. He said the word "poison" was not used, but the name of the preparation was given.

The Chair said he thought this point was covered in the Cullom Bill.

Mr. Emanuel offered as a substitute for the resolution that the Committee on Legislation be instructed to draw up a bill and present it to Congress, prohibiting the sale of all proprietary medicines containing toxic drugs, which did not bear a statement on the label as to quantity which was fatal to adult human life.

Mr. Good here made a remark which seemed to strike the members with great force. He said he did not see that this matter had been improved a particle as the result of all the discussion upon it, and he was satisfied that the Section could not reach a conclusion that would be satisfactory, and he therefore moved to lay the whole matter on the table.

This motion was seconded by half a dozen members and carried unanimously.

The Chair stated that the time had now come to have the symposium arranged for on examination questions, and that there were three papers to be presented before the Section on that subject, and then the matter would be open for discussion. The first paper was one by Mr. Sturmer, of Indiana, and he asked him to present it.

Mr. Sturmer read his paper as follows:

THE BOARD EXAMINATION: ITS INFLUENCE ON PHARMACEUTICAL EDUCATION.

BY J. W. STURMER.

For generations scientific workers, like the marine zoophytes which form the coral reefs, have been heaping fact upon fact. Thus a veritable mountain of facts has accumulated in every branch of science. No man can now make all knowledge his province, nor indeed all science.

As knowledge accumulates, it becomes more and more necessary that the process of learning, like that of food assimilation, be a selective process. Teaching a science subject therefore involves helping the student to make a judicious selection from the great wealth of material at hand. The object is not the attainment of the largest bulk of knowledge in the shortest time, but the attainment of the serviceable with the rigid exclusion of the useless. In practical life we find that a man's proficiency is not at all commensurate with the extent of his learning; and that, indeed, an efficient mind is a workshop rather than a storehouse. True, to do things one must have certain knowledge. But much of the knowledge which the old-time business man endeavored to keep in his head, the modern business man keeps in a card index or in a filing case. And in like manner,
much of the pharmaceutical lore might just as well be kept in book form, and repose on some handy library shelf until needed. When the business man adopted the card index and the filing case, he became vastly more capable. When the pharmacist gets over the notion that he must be a walking dispensatory—when he discovers that a mind can become so clogged with knowledge as to impede its functioning as a thinking organ, and learns to use reference books for reference—he also becomes vastly more capable. And as for education, the greatest discovery made in pedagogics was the discovery that the mere acquisition of facts and data did not constitute education. This applies to a pharmaceutical education as well as to any other.

In General Chemistry the instructor is now particularly concerned with principles and fundamental laws. More time is devoted to the theories of dissociation and of mass action, and less to such matters as the percentage composition of brass. An examination of the catalogues of our universities shows that General Chemistry courses are now in the main philosophical rather than descriptive. Details and mere facts not needed to shed light on laws or principles are not memorized, but are obtained from reference books as occasion arises. These remarks, with modification, apply to pharmacy as well.

Now I would not be understood as favoring the abolishing of all memory tasks. Nor even to restrict memorizing to the memorizing of laws and principles. I would memorize some facts; even a goodly number; but I would differentiate between facts which may help toward generalizations (helping to explain other facts), and facts uncorrelated, and valuable for their own sakes. Of the latter group pharmacy students should commit to memory only those facts which are required frequently in every-day work, and which when needed are needed promptly, as, for example, the doses of the common toxic drugs. But why students should be required to memorize names and data which might possibly be needed sometimes during their lives, but which in all probability will not, is a mystery to me. It seems such a waste of mental energy. Suppose our geography teachers had insisted that we learn the names of all the rivers, cities and hamlets in the Philippine Islands, in China, in Manchuria and in South Africa: and on the ground that at some future date wars might be fought in those distant lands, in which event the geographic names would be of assistance to us in following the campaign. Now, as a matter of fact, those wars were fought; we did follow the campaign; and with the help of maps got along passably well. In like manner we could get along passably well if many of the facts, near-facts, and fancies, which we memorized in our student days, had been left undisturbed in the text-books, to be looked up when needed. The average materia medica course includes something like 10,000 to 15,000 items to be memorized by students. No one can convince me that all this junk is of use in every-day work. Why should a
student—to cite only one example—be required to learn that in veratrum viride may be found jervine, rubijervine, pseudojervine, proto-veratrine, veratroidine and cevadine? There is only one reason why a student, knowing that such knowledge, or pseudo-knowledge, is absolutely useless to him in his life-work, will study such matters; and that is that he must pass his examination. And there is only one reason why some teachers insist on the memorizing of items of the aforementioned type: they presume (and on good grounds) that such knowledge may be required on a State Board examination. It seems that some State Board examinations are still based on the erroneous assumption that a candidate who has acquired a lot of out-of-the-way knowledge must needs be well versed in useful knowledge. That if he can give the botanical name of the plant on which grow jequirity seed, and can talk glibly of igasuric acid, he must be particularly well informed concerning those things which are of use in every-day work. Such reasoning is most fallacious. If a teacher in his own examinations deals with the remote, the insignificant, the unusual, his students soon "become wise," and give but scant attention to the important and the useful, emphasis in teaching notwithstanding. In other words: students can in a given time learn only so much; if they devote time to the useless, they will acquire that much less useful knowledge. This is axiomatic and needs no proof.

Some teachers deprecate that students generally seem to be so anxious to pass as to willingly forego the useful for the useless, if they expect the latter to be of assistance to them in the examination; so they advise their students against making special preparation for the State Board ordeal. Such advice may, under certain circumstances, be sound enough, but as far as I know, is never heeded.

This paper carries an implied criticism of State Board examinations. But it is not directed against State Boards in general, nor against the board of any one state in particular—it deals with general propositions.

Unfortunately a member of the Pharmacy Board does not, like the teacher, hold his position for a long period of time. When the examiner has acquired experience, and is beginning to do efficient work, he may be replaced; and not by an understudy, but by a man who has had no experience as a teacher, is not cognizant of the trend in pharmaceutical education, has no clear ideas as to educational standards, and is not familiar with approved methods for the sampling of a man's knowledge and ability—a sampling more difficult than the sampling of an ore, of a soil, of a lump of opium, or of a bale of drug (concerning which much good advice is freely offered in text books).

So to the younger Board members I submit this paper for consideration. I have tried to set forth the following:

1. That not only is the nature of the state board examination reflected in the curricula of some colleges, but also determines to a great extent the
attitude of students toward different branches of study in all colleges of pharmacy.

2. That the energy candidates expend in special study as preparation for this test before them, is in the aggregate astonishing as to amount.

3. That much of this energy is expended upon the unusual and unpractical questions, which fortunately are becoming fewer each year, but which still exercise a most pernicious influence in disturbing students' ideas as to what is worth while in pharmaceutical education.

4. That in pharmaceutical pedagogics we are placing more and more value on assimilated knowledge, as against knowledge in original packages; and that unless State Boards do likewise, they are bound to encourage quiz-compend study as against true education.

5. That the questions which encourage true education are also the questions which determine the candidate's real ability; and that the questions which call for the remote or curious or for text-book definitions, fail utterly as tests, and bring about the rejection of some of the ablest, and the passing of some of the least able of the candidates.

The board which has solved the problem as to what constitutes a real and just test by which candidates may be separated into competent and incompetent, has also solved the question as to how true education may be encouraged, and the spurious be discouraged. Pharmacy has no truer friend than such a board; nor has the pharmaceutical educator an ally more valuable.

Upon motion here by Mr. Hynson, the Presidents of the National Association of Boards of Pharmacy and the American Conference of Pharmaceutical Faculties were invited by the Chair to take seats upon the platform.

The Chair said he was sure the members would agree with him that the Section had a treat in store in the series of papers of which Mr. Sturmer's paper just read was a type. He then called on Mr. Arny to read his paper on the subject of examination questions.

Mr. Arny presented his subject as follows:

BOARD EXAMINATION QUESTIONS.

BY H. V. ARNY.

The symposium on board examinations, which appeared about two years since in the Druggists Circular, and also the series of papers on the same subject published during the past year in the Midland Druggist, seem to cover the matter so fully that the writer would not have had the temerity to occupy the time of this Section with his views on board examinations, except in response to a request from the Chairman of this Section for a paper on this topic.

The invitation was accepted chiefly to start, in this representative body,
a discussion as to the scope of board examinations, with the hope that such discussion may lead to progress in this particular field of pharmaceutical endeavor.

Without taking the time to go into details as to previous papers on the subject, the formerly-expressed views of the writer can be summarized in a series of questions.

I. *What constitutes an ideal board examination?*

This question can best be answered in the words of Dr. Whelpley (Proceedings A. Ph. A., 1905, 140)—"questions which any competent pharmacist can pass without any special preparation."

II. *Do any of the present board examinations come up to this ideal?*

The best answer to this is an incident told by a member of a board who said that a recent examination was tried by a man of sixty or over, a former registered pharmacist who had engaged in other business, allowed his registration to lapse and now after a decade or more in other lines, desired to take up his first love. He reported that the examination did not bother him much beyond questions relating to the present editions of the Pharmacopoeia and National Formulary; that he had done little by way of "boning for exam." When the papers were marked, it was found that this man came out second in a good-sized class.

III. *What kind of questions could a competent pharmacist answer without special preparation?*

To paraphrase a previous article (Druggists Circular 1909, 59) questions demanding among other things ability to think; acquaintance with pharmaceuticals, especially with view to proper dosage; knowledge of sufficient chemistry to foretell incompatibility, to distinguish chemicals by simple tests and to calculate molecular proportions; comprehension of materia medica covering constituents, doses and such individual peculiarities as count in selection or preservation of drugs; and, above all, a thorough conception of the prescription and of the many responsibilities that come to the dispenser.

Much is said these days relative to superiority of ability to reason over the memorizing of concrete facts, and with most such statements, the writer is in hearty sympathy. But as any good thing can be over-done, even so there is danger that we, in our zeal to increase the reasoning ability of future generations of pharmacists, may forget that the possession of quite a number of facts is essential to the successful man in any calling. To quote a previous article (Druggists Circular 1910, P. 185): "There is a tremendous number of facts that should be learned by students, despite statements to the contrary on the part of those of our teachers who promulgate the doctrine, that learning should be a plethora of observation and a paucity of memory work, and I venture to go so far as to say that the reason some of the exponents of this idea are great, is because their minds are stored with information beyond their fellows—and that gotten
as much under the midnight lamp as in the laboratory." But, on the other hand, an examination jammed full of facts is an abomination. Imagine any of us sitting down to answer such a question as:

"What is the solubility in alcohol and water of (a) boric acid; (b) gallic acid; (c) tannic acid; (d) lime; (e) hydrated chloral; (f) codeine phosphate; (g) codeine sulphate; (h) corrosive sublimate; (i) epsom salt; (j) terpin hydrate?"

If the intent of the examiner is to get the answer "insoluble," "sparingly soluble," "soluble" or "very soluble," the question is reasonable; but in cold black and white the question reads as if intended to ask for the exact number of parts of the solvent in which one part of the chemical dissolves.

This question of the "intention" of the examiner is another potent factor in the success or failure of the candidate. Recently there was submitted to the writer by a friend on a board of pharmacy, a set of questions which had wrought havoc in the class to which it had been submitted.

The highest made was 43 per cent. and the lowest 13 per cent.; while on the other branches excellent percentages were made; for instance one man made 95 per cent., 84 per cent. and 76 per cent. in three other branches and only 29 per cent. on the set of questions submitted. As an examination of the questions showed, that while the questions were difficult, they were not unreasonably severe, they were submitted as regular test to the writer's senior students with the result that of the twelve sets of answers, seven made over 70 per cent.; one man making 89 per cent.

The obvious conclusion was, that either the examiner's marking was too severe or the writer's too lenient.

The enthusiasm of the writer for examination made up exclusively of reasoning was dampened by the sudden appreciation, that while this may possibly be the ideal to which we should seek in some golden future, it does not fit the mentality of the present-day pharmacy student. In a previous article, the writer expressed his opinion that an examination could be devised consisting of prescriptions only, and yet including every branch taught in a school of pharmacy save microscopy and urinary analysis. Such an examination he tried last year with slaughter incredible, the only thing saving the boys being their good yearly averages. That the boys were better than the average was shown by the fact that all save one easily made the subsequent examination of the State Board of Pharmacy.

Speaking as an individual teacher, the problem is to get the boys to think and for this reason, the Board Examiners can find no better field for improvement of the quality of candidates than a wise and gradual increase in the number of reasoning questions.

IV. How can board questions be improved both in quality and uniformity?
This can be accomplished, as has already been suggested by others, by the establishment of a Central Question Committee, appointed by the National Association of Boards of Pharmacy, and consisting of members of the boards; this central committee to ask contributions of questions from all interested, (notably from board members and from teachers) the task of the committee being to group these questions into harmonious sets. A set of these questions constituting the scope of the average board examination to be furnished to all the boards going into the plan, and used by these boards on the same day; this making a union interstate examination similar to the union college-entrance examinations, which prevail in the northern section of our country. Such a plan would not only insure uniformity, but would also largely contribute to solve the vexatious problem of interchange of certificates.

As to objections to the plan, several men of straw could here be erected and immediately knocked down, but it is deemed wisest to answer outside criticisms, rather than those of the writer's own making.

The Chair called for the third paper of this series, one by Mr. Kalusowski, of Washington City, and that gentleman presented his subject as follows:

ON SOME DEFECTS IN EXAMINATIONS.

BY H. E. KALUSOWSKI.

The methods of examination of students of pharmacy as they are usually followed are not satisfactory nor conclusive: they cannot be criticised upon either the scope or variety of questions; they are open to criticism, however, upon what they often fail to disclose, which is, the measure of a student's attainments. The conclusions that are drawn from the answers given in a written examination are sometimes far from being correct. A student possessed of the faculty of memorizing, and with a fair ability to transpose his recollections to paper, will answer a series of questions in such a manner that his answers will receive high ratings; yet the same kind of a student in a dispensing department of a pharmacy will not always prove satisfactory; the inefficient character of his work and his inability to apply the fundamentals of pharmacy so as to produce the best results are frequently in evidence.

There is another type of student. The rating given to his written answers has just earned him the passing mark, his style of composition is labored in the expression of ideas, and as a result what he wishes to convey in his answers is somewhat obscure, differing from his more brilliant colleague, whose answers read as if they had been transcribed from a text book. Turning for comparison, to their work in laboratories, it is found that in the general result there are some differences. In the case of the first student we find as a rule his work is done rapidly; apparently it has been well done. A closer inspection soon makes a decided impression that some-
thing is wanting; checking up his work, it is soon found that many things are deficient. This feeling is absent when the work of the less brilliant student is inspected. There may not be quite as much accomplished, but what is done appears to be well done, and when closely inspected it leaves an impression of completeness.

The two extremes are taken to illustrate the fact that in an exclusively written examination we have to deal with this condition: that from some students endowed with a fair amount of the faculty for memorizing and some ability to fairly well transpose upon paper what they have memorized, the examiner will receive an excellent paper and the answers will be rated accordingly. In the other case we have to deal with a student who is not gifted with any great amount of the faculty for memorizing. His tendency is to arrange his mental stock in some kind of order and draw upon this to work out an answer to the question before him; his faculty for transposing his conclusions upon paper is not very good; he has not the gift of writing, yet we find in the sometimes obscure and frequently defective methods of expression evidence that he has reasoned out his answers. But as the written examination has been made the final test of their respective attainments, the examiner is placed in the position where a rating, high or low, is given to a paper, which, in many cases, does not indicate the actual attainment and ability of a student. Another condition which impairs the value of a written examination is the wide difference in the character of the answers made by students having apparently the same degree of attainment. While this is altogether a personal condition, it is a condition that is difficult to consider and one which necessitates much thought in the rating of answers. A nervous student will, as a rule, show a falling-off in his answers as compared with a phlegmatic, unemotional student. In a written examination extreme nervousness on the part of students is a frequent occurrence. The thought of having to write answers to a given number of questions and complete them within a set time seems to unnerv some students to that degree where they apparently become incapable of doing anything.

Oral examinations are less trying to this class of students. It is an easy matter for the examiner by words of encouragement to give a nervous and merely demoralized student a feeling of comparative ease and restore confidence in himself. An oral examination, while it offers some advantages, is open to this objection, that it is difficult, in fact impracticable, to arrange a series of questions for any considerable number of students which will be of equal educational value and in which each student is placed on exactly the same level, as is obtained by a written examination. In this respect a written examination has the element of equality.

A laboratory examination that requires the compounding of a series of formulas has this value, that it will bring out what theoretical knowledge a student has acquired; it will also serve as a test of his efficiency in putting
his acquisitions into results. It may be urged against the value of a laboratory examination, that it is possible for a student to acquire a certain amount of a kind of mechanical knack by which he can after a fashion compound a formula without knowing much of the fundamentals of pharmacy. No one will deny that there is force in this objection; it is, however, an easy matter to select formulas of such a character that unless the student has a good knowledge of the art of pharmacy and is well grounded in chemistry, he cannot with all his "rule of thumb" practice produce a satisfactory result.

A laboratory examination, restricted to a limited number of formulas which have been selected because they require a knowledge of the theory and practice of pharmacy, is, in conjunction with a written report explaining and describing the methods followed to produce results, of much value. Among other things which may be said in favor of such an examination is that it is more evenly balanced, and a nervous student is soon set at his ease, any defects in his ability to compose written answers which would otherwise be exaggerated through his self-consciousness being in a measure overcome or forgotten during his absorption in practical work.

While a final test of some kind, written, oral or practical is indispens-able, such a test, whatever it may be, should take into consideration the records made by the student during recitations, and the character of his work in the laboratories, as to whether the work has been well done, giving due credit for neatness and celerity. Notice should be taken if his work was done by an orderly application of principles, chemical and pharmaceutical, involved in the processes, or whether it was simply intended to report a large quantity of work done without regard to the final character or condition of it.

A laboratory examination confined exclusively to the preparation of a number of formulas is without great value unless it is accompanied by a written narrative of how the work was performed and why certain things connected with the work were done. With this form of examination the examiner is placed in a better position to pass upon the qualification of a student. That there are inherent defects in any system is admitted but by some such combination as that mentioned it is believed that it will show the general deficiency of the student and give less prominence to the faculty of memorizing.

A defect of another character common to written examinations is frequently found in the selection and grouping of questions and at times some obscurity in their phraseology by which the scope of the question is not grasped by the student.

A block question with its subquestions should be so worded as to leave no doubt of its meaning and should be confined to one topic and not cover a series of unrelated subjects, and the subquestions should be arranged in a systematic order so as to cover the chief points of pharmaceutical in-
terest in the topic selected. A question arranged upon such a plan generally places difficulties before those students who have memorized more or less of the contents of a quiz compend. The following types of questions will serve as a fair illustration:

How is Ferric Chloride Solution prepared?
What are its physical characteristics?
How much Iron will be required to prepare 125.00 grams of the official solution?
By what tests can it be shown that Nitric Acid and Ferrous Iron are absent?
How is the official Tincture of Ferric Chloride prepared?
Why is it directed to keep this preparation for three months before dispensing?
Name some of the common incompatibilities with the Tincture and state how they are manifested?
What is the dose of the Tincture and how should it be taken?
A block question of this character will fairly well exhaust one topic, and if a student answers it correctly or seventy-five per cent. correctly it may be assumed that he knows something about that particular subject.

In a practical examination the object should be to ascertain his familiarity with proper methods of dispensing prescriptions and compounding formulas so that their intended therapeutic effects should be presented in their fullest efficiency. The skill of the candidate in a practical examination should not be tested by a series of formulas whose chief characteristic is their heterogeneous composition which frequently admit the concealment of defective manipulations, but by formulas for compounds usually dispensed, such as emulsions, pills, solutions and ointments—mixtures should be omitted. Under emulsions two types are available, one with either a fixed or volatile oil with a syrup and hydro-alcoholic fluid; another type would include an emulsion of some fixed or volatile oil or a mixture of both and to contain some solid substance such as salol in a vehicle of syrup and water. Under pills, a mixture of salol, quinine and acetanilide or other bodies without any adhesive qualities; the formula should not indicate any more than that the pills when ready for dispensing are to be white and not bulky. Volatile oils and oleoresins may be ordered in pill form without indicating excipients.

Formulas for solutions should be such that some knowledge of chemistry is necessary to compound them. A formula of this type while simple is generally a fair test: Of salicylic acid, bicarb. soda and water, a colorless solution is required: Tincture of nux vomica fl. 5iv, potassium iodide 3ij, mercuric chloride gr. ij, water enough to make fl. 3iv; a solution without any precipitate is required. In the choice of ointment it is always well to select some compound that contains several incompatible substances and indicate the quantities in percentages, such as for example in
the following: "Make half a troy ounce of a smooth ointment using benzoated lard as the base which will contain 5 per cent. ext. opium, 3½ per cent. tannin and 1 per cent. lead acetate, or a formula may be submitted for an ointment to contain a soluble salt and a fat with lanolin.

A test of the student's knowledge of weights and measures can be brought out by something like the following. Prepare two fluidounces of an aqueous solution of mercuric chloride so that when three fluid drachms are added to 500 Cc. water the mixture will make a \( \frac{1}{4000} \) solution of mercuric chloride.

When suppositories are included, besides some ordinary incompatibility such as may occur between extracts that contain tannin and those that contain alkaloids, weights of finished suppository should not be given; the formula should only say use sufficient \( \text{oil} \) of theobroma to make so many rectal suppositories U. S. P. weight and dimensions.

These examples are given to show the object in view, which is not to confuse a student of the average ability by presenting him impossible puzzles but by giving him something to reflect upon and bring into play his knowledge of the theory and practice of pharmacy.

Upon the completion of his practical work properly labeled with identification mark or symbol he should write a brief account stating what plan and order he followed and give a reason for each step that was taken; if the formulas called for metric quantities he should be required to give their equivalents in apothecaries weights and measure.

By a combination of this kind, and a written examination confined to a certain number of topics, the examiner can according to the results he obtains form a just conclusion regarding a student's qualifications, and a student otherwise satisfactory but deficient in ability to transpose his thoughts to paper is placed in a position where this deficiency is more than balanced when he can give a manual proof of his knowledge. A combined examination of this character, while it is far removed from perfection and has some of the defects that are inseparable from any test of ability which depends upon a student to show in a restricted period of time and under conditions which he feels are unfavorable to him, will prove a fair measure of his attainments.

It can be said of this plan that it is in its general results more evenly balanced and only operates disadvantageously to the student who depends upon qualifying himself for his examination by two or three week's cramming with a quiz compend.

The Chair announced that these three valuable papers were now open for discussion.

Mr. Mason opened the discussion, and began by saying that State Board examinations comprised one of the most important subjects that could possibly be discussed, for upon proper examinations depended the character of the men who were admitted to the ranks of pharmacy. It was also a
subject fraught with great difficulty. During the last two or three years, he said, the journal with which he was connected had been, so to speak, endeavoring to pass different State examinations, as some of the gentlemen present knew; that it had been printing the board examinations and answering the questions itself. He himself had not done this work, but one of his assistants had been preparing these answers, and he had kept in close touch with the work. He had found, as Mr. Sturmer and Mr. Arny had pointed out, that the great majority of questions asked by boards of pharmacy were immaterial, and not of a character to test the real ability of the candidate. As Mr. Sturmer had said, every careful pharmacist should know by memory the dose of morphine, opium, and things of that kind; but behind the prescription-counter, when a prescription was presented, or when a formula of the U. S. P. was to be dispensed, he thought surely it would not be expected that the pharmacist should do this work from memory, but would naturally depend upon the reference-book. He agreed with the writers of these papers that the thinking and reasoning powers of the student, based on his knowledge of the fundamental principles of pharmacy, chemistry and allied sciences, should be developed, and questions should be asked which would bring these qualities into play. This was not the case with the examinations as ordinarily conducted. Mr. Mason admitted, however, that it was very difficult to say just what form such examinations should take. Even in the case of careful educators, where they had had a student under constant surveillance for two or three years and were familiar with his personality and work, it was difficult to draw up an examination to test the real efficiency of the student. And if the teacher, who was accustomed to test students, had this difficulty, naturally it must be accentuated with the Board of Pharmacy, whose members knew nothing of the personality of the applicant, and were called on to test the efficiency of perhaps 50 or 60 men at one time.

Mr. Mason went on to say that he had been much impressed with the recommendation of Mr. Arny that a central committee be created to draw up a model examination for use by boards of pharmacy. This was not a new idea, but he considered it a timely one. It might be that some members of the boards would fear to lose their individuality by this plan, but he thought the idea was well worth trying. But why not go a step further, he asked, and have a joint committee, appointed from the Conference of Faculties and the Association of Boards, thus giving the teachers "a whack at this thing." The boards and the colleges were getting together through the syllabus and in other ways, and the future of pharmaceutical education was largely dependent upon such harmonious and co-operative action. He thought such a joint committee would be peculiarly fitted to draw up a model for board examinations. He did not mean that the board should be bound by such action, but it would be at least of some suggestive benefit, and have some educational value. He was firmly convinced that the
average State Board examination was not what it ought to be, and must inevitably lead, as Mr. Sturmer had pointed out, to the frequent rejection of really good candidates because they could not answer questions asked about obscure and inconsequential matters, while the "crammers" of the quiz compends would sail through with flying colors.

Continuing, Mr. Mason passed to another phase of the subject, and said he believed that Board examinations should, so far as possible, duplicate the actual conditions in the store. He thought, therefore, that practical questions ought to be asked by the Board, and that the practical examinations which had been conducted by the Boards in recent years were a step in the right direction. "Give a man a book and everything else he needs," said Mr. Mason. "Don't leave him helpless, and relying solely on his memory to solve a problem presented to him, but give him the books, and put questions to him so that he will not have to look up isolated facts, but call on his powers of reasoning and his knowledge of pharmacy."

Mr. Engstrom was the next speaker, and started out by saying that as the professors had had their inning, and the press theirs, he thought the Boards of Pharmacy should have something to say in regard to the subject of examinations. He said the Boards had been discussing examinations in much the same manner as the suggestions that had been offered here, and that he could go further and say that the Boards were trying to get so near together that every State would, in its examination, pay due regard to the three points that had been emphasized this morning as necessary to determine the ability of a man to be a pharmacist in any State in the Union—the three methods of examination, written, oral and practical work; and that the majority of the States belonging to the Association already had this feature. Referring to conditions in Massachusetts, Mr. Engstrom said that in the report of the State Board to the Governor they gave a statement or outline of the examination required. He then proceeded to read at length from the regulations on this subject prevailing in his State, showing how the attempt was made to get at the candidate's real knowledge, rather than test his memory merely. He gave some illustrations of the character of questions asked, and related some experiences showing where the student could memorize the words of the Pharmacopoeia, but could not put the meaning in concise form of expression, because he had not been trained to think. Mr. Engstrom said the Boards generally were doing all they could to eliminate quiz compends and to get at the real facts as to the candidate's knowledge, so that they would know when the candidates were passed that they were safe to be placed in charge of drug-stores in their respective States.

Mr. Hynson asked Mr. Engstrom if he had any statistics regarding the number of failures before and since the adoption of that standard, and Mr. Engstrom replied that this was a matter that depended largely on conditions, and there was very little difference, he thought. He said that
they had had thirty examinations last year, and he did not believe any college professor was called upon to read thirty examination papers, with the numerous questions involved. To write out these 30 papers required a great deal of thought and carefully going over each question, to avoid criticism by the outside world, and by the students themselves.

Continuing, and referring to the proposition to have the National Boards submit a form of questions, Mr. Engstrom said he did not regard this as practical, for the reason that the Boards of the respective States must take into consideration the environment of the student that came up for examination. For instance, in certain States they had a prerequisite law applying to college graduates only: a man must be a college graduate before he came before the State Board for examination. But in the majority of States that requirement did not exist. He thought these questions must be prepared to make a fair test of the candidate, and the Board should be careful to see that the questions asked were not so high above the heads of the boys that they could not cope with them; they should be given a chance to pass. Mr. Engstrom likened the Board to a sort of national balance-wheel on this subject, as between the different States. Recurring to conditions in Massachusetts, Mr. Engstrom said that 491 applicants were before the Board last year, in 30 different examinations, and that 125 of these had been passed as registered pharmacists, 198 as assistant pharmacists, and 168 failed. Under their system, if the candidate for full registration did not attain 75 per cent. on his examination, he was granted an assistant's certificate if he attained 60 per cent. There had been a great demand for drug-clerks in the State, and the law allowing the giving of assistant pharmacist' certificates was passed to relieve this situation.

Mr. Payne said he had listened with a great deal of interest to the papers read, and the discussion up to this point, and he felt that a great deal of valuable information had been given, but there was one point that had not been brought out, and that was the limited time the State Board could remain in session, and the limited number of questions that could be put—especially in dealing with a large number of candidates at one time—as had been his experience in Georgia in the fifteen years of his service on the Georgia Board, where there had been as many as 120 candidates before the Board at one time. No Board wished to ask so many questions that it was a hardship on the mental endurance of any young man to take the examination, nor was it desirable to have the examination so long that it would be a terrific physical strain on the examiner who marked up the papers in the limited time available. The item of expense to candidates was another thing to be considered. It might be easy enough, he said, to take a single candidate and find out what he knew in a short time, and perhaps with but little questioning; but when an examination paper was gotten up for 120 men, to find out what they all know, it became a very serious problem, and one that required a great deal of
thought and care. His experience had been that there were certain memory questions that should always be asked, to develop the applicant's knowledge concerning certain things, that every one should know.

Mr. Hynson, speaking of Mr. Kalusowski’s paper, said there was a wide difference between the man that was good on technique, but had no real mental equipment, and the really qualified man, and said his experience had been that if a man had mental capacity to stand well in chemistry, materia medica and the theory of pharmacy, he was almost always a good practical man, whether he had drug-store experience or not. He was opposed to too much practical work in the examinations, as the conclusions drawn therefrom were liable to be erroneous. It was impracticable to assay each pill, for instance, and too much reliance should not be placed on this feature of examinations.

Mr. Flemer said he wanted to indulge in a little retrospection: That he had had four or five years' experience on boards of examination, and he had reached certain conclusions that he thought it would be well to speak of at this time. He referred particularly to the purpose and scope of board examinations, and said he believed the time would come when such examinations would be, not so much an examination by the board, as by a surveying board. He said the purpose of the examination should be, first, to find out whether the statements with reference to age, practical experience and preliminary education were all fulfilled. He expressed the belief that, in the future, none but college graduates would be capable of passing the rigid board examinations in the more progressive States. Mr. Flemer said their experience with oral examination had not been satisfactory, for the reason that it had gotten them into trouble with the courts. The materia medica examination had usually been conducted orally, but one of the candidates took exception to it, and claimed that the questions asked him were not the same as those asked the other candidates, and he took the case to court and won out; and since that time the board had not conducted oral examinations in Washington. He expressed the opinion that no man could tell by written or practical examination only, the capacity or incapacity of the candidate. He believed that far more could be discovered as to the candidate's real ability, and in a great deal less time, by a few well-directed oral questions, and it was unfortunate that they were limited to written examinations for the reasons given.

Mr. Mankin said he thought these most excellent papers that had been read before the Section ought by all means to be published, so that other boards and colleges might have the benefit of them. He thought there was an erroneous impression in regard to the boards of pharmacy and the colleges in the suggestion that there was a disposition on the part of the colleges to so instruct their students that they could pass the board examinations. He said he thought the colleges were getting broader and broader in their examinations, and that the boards of pharmacy were
getting closer to them; and that if more such papers as those presented here could be brought before the members, and the examinations made broader, plainer and more practical, and the college professor brought into examination work, it would be a strong move in the right direction.

The Chair stated that if there was no further discussion, the papers would be received to take their usual course, and referred to the Publication Committee.

Mr. Seltzer, referring to the matter of oral examination, said he thought both systems were very important, and he commended the suggestion of the Massachusetts Board in giving notice of what was expected of them as a capital idea, and thought the Boards of other States should take that up.

Mr. Arny here entered an earnest protest against Mr. Mason's suggestion that the school men be represented upon the proposed central committee on examination questions. He said he did not want this done, because everybody knew that the National Association of Boards of Pharmacy had enough capable men in it to deal with this question satisfactorily, without the assistance of the school men on this committee. It was all right if the Boards of Pharmacy wanted to invite questions from the school men, but he was opposed to the latter "dabbling" with it officially, or in their examinations, as it was a matter peculiarly for the Board.

Mr. Mason was equally earnest in his protest against Mr. Arny's position that the teachers should not be mixed up in this matter for political reasons. He said he meant "political" in a broad sense; that there had been a feeling sometimes that if the teachers were involved they would in some way favor themselves at the expense of the Board. He said he thought these fears were rather exaggerated.

Thereupon, Mr. Mason moved that the incoming chairman of this Section appoint a committee of ten men, five of them to be members of Boards of Pharmacy, and five of them college professors; this committee of ten to draw up during the year a set of specimen examination questions, to be presented before this Section next year for discussion—simply for discussion and enlightenment—at the joint session of the three bodies now holding this session. He said he did not mean a set of questions necessarily to be used by any Board, but simply to be drawn up for its educational benefit, and as a basis for discussion next year. He thought there could be no possible objection on Mr. Arny's part to having the teachers represented on such a committee. It was especially desirable to have the teachers represented, in view of the present tendency of the Boards and Colleges to get closer together through the Syllabus, and the effort to harmonize things so the Boards would regard certain subjects much the same way the colleges were teaching them.

Mr. Payne offered as amendment to this motion that there be established a system, or some arrangement, to serve as the basis upon which a selec-
tion of questions might be made. The questions themselves would not amount to much, because they could be used but once, whereas a generally understood basis for such questions might prove very valuable and useful.

The Chair suggested that this might complicate matters, and that the best basis of selection would naturally come out in the discussion of the suggested questions before the general committee.

Thereupon Mr. Payne withdrew his proposed amendment.

Mr. Taylor seconded Mr. Mason's motion. He said he did not want to discuss this question, but it was one of the "livest wires" that had been touched at this meeting. He expressed the opinion that the teachers who might be appointed on this committee should be teachers who were not also members of Boards of Pharmacy.

Mr. Mason said he would accept this suggestion.

The chair stated that the motion was, that the Chairman of this Section appoint a committee of ten members, five of whom should be members of Boards of Pharmacy, and five of whom should be members of College Faculties and not members of Pharmacy Boards, this committee to report at one of next year's sessions, with a specimen set of examination questions.

And the motion was so put and carried.

The Chair said he would now entertain a motion to refer the papers read to the Publication Committee, in the ordinary course.

A motion to this effect was put and carried.

The Chair called for a paper by Rufus L. Lyman on pharmacology as a curriculum essential, and that gentleman presented his subject as follows:

EXPERIMENTAL PHARMACOLOGY AN ESSENTIAL IN THE PHARMA-
CEUTICAL CURRICULUM.

Rufus A. Lyman, Director of the School of Pharmacy, University of Nebraska.

I have been requested to express my views upon this subject. I make no claims to the title of a pharmacologist. I wish to be known as a physician interested in both medical and pharmaceutical education. I suppose because of the interest I have manifested along these lines, I was asked a short time ago, to organize a school of pharmacy in the University of Nebraska, where it was felt by both educational and professional men that such an institution was needed in order that the young men and women of our state might receive more efficient pharmaceutical training. My remarks are inspired by my experience as a student of medicine of ten years ago and as a practitioner, and a teacher of medical and pharmaceutic students since that time.

In a former paper, I have quoted the following statement made by Professor J. T. Halsey of Tulane University. "A study of the current and past therapeutic literature will, I believe, convince any doubter who possesses sufficient knowledge to enable him to form an intelligent opinion,
that there is no branch of medical science, other than therapeutics, wherein medical men display a more culpable and harmful ignorance of essential facts than is the case with pharmacology. Without an exact knowledge of the pharmacological action of some, at least, of our important drugs, a physician must become and remain an empiricist, one shooting in the dark with deadly weapons whose range and power are unknown to him,"—a statement every phrase of which every medical man knows to be brim full of truth.

Many have attempted to explain the cause of the present chaotic condition of pharmacology and therapeutics. Medical men everywhere, and in some cases men prominent in the profession, have attributed it to the fact that the teaching of prescription writing has been neglected in our medical schools. In fact, in recent years more criticism from certain sources has fallen to the lot of this minor course than to the whole of the remainder of the medical curriculum. To a medical pedagogue such criticism is amusing. Even in these days of antipolyphony the teaching of the elements of prescription writing is necessary and practice in the same is desirable, but one cannot acquire a knowledge of the physiological action or therapeutic application of drugs through any amount of such teaching and practice.

To appreciate the present state of the medical and pharmaceutical sciences and the ignorance that prevails so largely, within the profession it is necessary to recall a few historical facts. As every one knows, historical medicine began with the Egyptians. We infer, however, that medical practice must have begun with the origin of the human race coincident with the liability to injury and sickness. In the beginning the cause of disease was probably attributed to the indwelling of evil spirits. One may reasonably infer this from the fact that it was so believed later in historical times and the belief is still prevalent among savage tribes and semi-civilized nations. Naturally the original method of treatment consisted of prayers and incantations. The making of noises and the application of fire were used to drive out the demons from the afflicted. Material methods of treatment came to be used. By accident it was found that certain chemicals and plants seemed to be of value as means of cure. Curiously enough, the more disgusting and nauseating the substance, the greater was believed to be its potency in the treatment of disease. A materia medica was developed of such a disgusting nature that civilized people must revolt against it. This came in the eighteenth century. The time was ripe for homeopathy. It came. The reaction set in. The pendulum swung to the other extreme and the early years of the nineteenth century witnessed a period of nihilism. The great Skoda (1805–1881) was its most ardent advocate. However, it was he who paved the way for the rational study of pharmacology and therapeutics. He introduced the methods of auscultation and percussion making it possible to
study more accurately the effects of disease and consequently the action of remedies.

In 1817 morphine was isolated by Sertürner. Thus a definite plant product was substituted for an indefinite crude drug. Animal experimentation was begun and gave rise to modern pharmacology.

In a recent article by Doctor Horatio Wood, Jr., entitled, "The Value and Limitations of Physiological Standardization," he points out the fact that pharmacology is a new science, that the first pharmacologist in the modern acceptation of the term, is still living and teaching. He discusses the danger of error in the biological test and shows the necessity of its use in the standardization of certain pharmacopoeial products and the testing of the efficiency of others. He calls attention especially to the work done upon digitalis and ergot by Americans and Europeans, of the new methods introduced by Doctor Reid Hunt in the study of glandular products and to the fact, that the problems which the pharmacologist is asked to solve at once, make a herculean task, surrounded by numerous difficulties.

To one who has studied the subject ever so superficially, it is evident the treatment of disease by drugs is to be made rational by introducing into our schools courses in experimental pharmacology. I believe the lack of such training is the greatest defect in our present system of medical education. A student may be very well trained in the fundamental branches of medicine, such as anatomy, chemistry, physics, physiology, bacteriology and pathology; he may be skilled in modern methods of physical and clinical diagnosis and still know nothing about the changes induced in the physiology of the normal animal body by the introduction of drugs, and much less about their use in diseased conditions. For example, as a medical student I remember the importance that was placed upon strychnine as a therapeutic agent. I was taught that it was a tonic par excellence; that it increased all the functions of the body; that it increased the activity of the heart; that, in large enough doses, it induced convulsions; that it was useful in diseases of the heart, in certain digestive disturbances, in emaciated conditions, etc., etc. In a like manner I was taught the physiological action and therapeutic application of a hundred other substances. When I was through with it all it seemed the most unsatisfactory subject in the medical curriculum. If in the beginning I had been given a frog and told to inject a certain quantity of strychnine into the lymph sac and had been instructed to study the symptoms, and with the onset of convulsions had been shown how to do a series of simple operations which show conclusively that the convulsions are due to the action of strychnine upon the spinal cord and not upon peripheral nerves, motor end plates or muscles; and more than that, if I had been shown that this action upon the cord was due to its effect on certain elements in the cord and not upon others, I would have realized that strychnine was a body which produced
marked and definite physiological changes. Having found that its presence (in some unknown manner) caused symptoms which indicated stimulation at a certain point, I would have been in a position to use strychnine rationally in any diseased condition where it might be desirable to increase the activity of the central nervous system and those functions which are controlled indirectly through it. I would also have had a hint as to its possible uses in the treatment of depressing poisons and as a synergist to the action of other drugs. Strychnine would then have been a reality to me, a useful tool, something I could have used with satisfaction. That simple experiment would have opened up a new field of thought. From various sources we hear expressions of surprise that physicians prescribe proprietary remedies. There is no occasion for surprise. With the training they have received in our medical schools and which they still receive in the majority of them, it is a surprise that pharmacopoeial preparations are prescribed at all. If a school does not furnish a foundation upon which a superstructure may be built, graduates in medicine must still learn therapeutics from the label of the proprietary medicine bottle. This lack of pharmacological training is manifested on every hand among surgeons and medical practitioners of high standing. This leads to the most absurd mistakes. For example, a short time ago I was asked by one of the leading surgeons of Lincoln to step into his operating room and see one of his patients, "who was not doing very well on the table." I found a man undergoing an operation for ruptured appendix. The abdomen was full of pus. The patient was in a condition of collapse before the beginning of the operation. The heart beat was just discernible. The attendants had just injected subcutaneously into the axilla one quart of physiological salt solution, to which six drops of adrenalin chloride had been added. They were beginning with the second quart so treated. The surgeon remarked that the heart did not respond to the adrenalin. Of course it did not. The active constituent was oxidized and rendered inert long before it reached the heart. The patient died. Again, there is an obstetrician in our city who has no superior in the middle West. I lately discovered that he makes a routine of giving five drops of adrenalin chloride per os following labor, to cause uterine contraction and to prevent hemorrhage. Of course it is destroyed before it reaches the blood vessels of the mucosa. I know of another man who gave cocaine by the mouth and was surprised that he did not get local anaesthesia in the skin. I saw another successful practitioner use strychnine hypodermically in order to lessen the severity of an epileptic convulsion. Such examples might be quoted ad infinitum. Such errors would not occur had these men had pharmacological training and been able to appreciate the pharmacological point of view.

One physician, a graduate of ten years ago from one of the famous eastern medical schools, now a man well known in our state and a member
of the faculty of the University, tells me whenever he has opportunity, that he does not believe students understand pharmacological experimental work. He is of the opinion that it is beyond them. He maintains that they go through the experiments as a matter of routine. This is not so. The average student is a thinking being, his thoughts only need directing. From his pharmacological experiments and observations he will draw conclusions as to the therapeutic uses, which as a rule are surprisingly accurate.

My remarks have been made, chiefly with the medical student in mind, but they are just as applicable to the training of the student of pharmacy. As pharmacological methods are elaborated and perfected, they will become more valuable in pharmacopoeial standardization. I do not mean that we shall make expert pharmacologists out of our pharmacists. That is not possible; but every pharmacist should understand the general principles of the biological test just as he does the general principles of the chemical tests of the Pharmacopoeia. Likewise, experimental toxicology is an important subject to the practical pharmacist. In addition the study of pharmacology has an obvious educational advantage and must increase the standing of the pharmacist with physicians and with the people of the community in which he lives. Comparatively few medical schools, at the present time, offer courses in experimental pharmacology and I believe there are no pharmacy schools with the exception of Nebraska. I may be mistaken in this matter and beg to be corrected, if I am. My information has been obtained from the catalogues of the leading American schools and my time has been too limited to write to representative institutions. Pharmacologists are scarcely obtainable at any price because they do not exist. I suppose there are a dozen men in the United States who can be called expert pharmacologists, perhaps a few more or a few less, the number is immaterial. The question is then, how can we install pharmacological teaching in our schools. While pharmacologists are few, physiologists are more plentiful. I believe there are very few state institutions, even in the newer west, that do not have a trained, experimental physiologist. The first pre-requisite of a pharmacologist is of course, that he be a physiologist, and pharmacological work is the legitimate field of the physiologist. No apparatus is needed, which is not found in a fairly well equipped physiological laboratory. I can see no reason, why at least the fundamentals of pharmacology could not be taught to students of pharmacy. They should at least, be shown that drugs do induce physiological changes, that these changes are induced by action upon certain part or parts of the organism and that such action may be used as a means of classification and standardization. If such a movement could be made general, it would give a wonderful impetus to a science, which is full of promise for improving both medical and pharmaceutical practice. To me, it is a most significant fact that Ehrlich should, in the prime of his life,
turn away from the subject of immunity and serums, to devote practically all of his time to the study of pharmacological problems.

Pharmacy and medicine have a common aim, viz., the conservation of the public health. In recent years we have witnessed a marvelous campaign, waged by the two professions against quackery, graft, disease and the use of narcotic and habit-producing drugs and food preservatives, adulterants, etc. In this work the leaders of the pharmaceutical profession have not taken a place second to medical men. As time goes on, I believe both physician and pharmacist must assume more and more the role of teacher, and cooperate with the teaching profession, and use that profession, in disseminating the necessary knowledge to the public. An interesting experiment is being tried in Nebraska, with success. We have a State Teachers' Association of 4000 members. It is composed of twenty-one sections. Two years ago, a few philanthropically inclined individuals requested that a section be added to the association, which should have for its object the discussion of subjects which concern the public health, especially the health of school children. This was done. The section was called the Section on Medical Education. During a three days' session of the association many sections must be held at the same time. Nevertheless, since the organization of the Medical Section 600 teachers have been in attendance at each meeting. The problems are presented to the teachers by the foremost medical and pharmaceutical men of our state, in such a way that the teachers can use the material to advantage in the school room. I speak of this matter because I believe it is one of the things to which, we as physicians and pharmacists should give our serious attention. I will admit, however, that I have a certain feeling of pride in the novelty of the scheme.

I would feel justified in giving courses in pharmacology to pharmacy students, if it were for no other reason than, that they might see for themselves the harmful effects of the groups of drugs, previously mentioned in order that they may be in a position to authoritatively instruct the citizens of the respective communities in which they live.

I am not in sympathy with some recently expressed views that the education of the pharmacist should be broader in order that his field of operation in a professional way, may be extended, but, I do believe in a broader, more thorough, and more scientific training, in order that his efficiency and usefulness may be increased in the field in which he now operates.

Mr. Taylor said that he found himself in a delicate position; that he felt he ought to keep still, yet his manhood prevented his doing so. He said that there were upon the program quite a number of important papers, and the session was now down to the time of adjournment, without any opportunity to present them; that men were here with work
blocked out and given a place on the program for a certain time, with no opportunity to present their papers. He regarded the paper just presented as one of the most important that had come before the Section at this time, but he was reminded of an expression he had once heard, that "it was better not to know too many things than to know so many things that were not so." He said this paper deserved the most careful consideration, and he deplored the idea of its going into the Proceedings without being thoroughly discussed. He would not hesitate for a moment to have it go into the Proceedings if it could be properly discussed, but it could not be at this stage. The whole article, in his opinion, was filled with a misconception of what the American Pharmaceutical Association had been doing in recent years. He thought the definition of "pharmacology" as outlined in the paper was diametrically and wholly and absolutely opposed to the Syllabus that had been adopted by this Association, after five years' work on it. He expressed the hope that the writer would not misconstrue him, because he had not the slightest disposition to discuss the paper on account of the limited time; and he hoped that no record would be made of his remarks in this connection. He did not know what solution could be offered of the difficulty, unless the paper should be referred to some committee, with power to confer with the author and bring it up at some future meeting.

Replying to a question by Mr. Hynson as to the specific point of his objection, Mr. Taylor said his chief objection was to the position in which the section found itself, with a long program, with other papers on it of importance equal to that of those already presented, and with an important paper before the Section now, which could not be discussed, and confronted with the possibility of its going into the Proceedings as an authoritative utterance from this body.

Mr. Lyman said he thought he understood the position of Mr. Taylor, and was sorry that he had not made his paper clearer on this point. He confessed that he had probably made an infelicitous use of the word "pharmacology," and declared that the idea that he had in mind was that of Mr. Taylor—that such represented the spirit of his paper.

The Chair stated that, as he understood Mr. Lyman, his paper was really on the subject of Pharmacodynamics, or what had been known as "experimental pharmacology." He said if there was no objection the Chair would entertain a motion to make some disposition of the paper.

Thereupon, on motion of Mr. Emanuel, seconded by Mr. Burge, the paper was ordered to take the usual course.

The Chair called for a paper by W. A. Puckner on the abuse of chemical formulas, which he said would be read by Mr. Motter.

Mr. Motter presented Mr. Puckner's paper as follows:
THE ABUSE OF CHEMICAL FORMULAS—AN APPEAL TO TEACHERS.

W. A. FUCKNER.

To the tyro in chemistry, chemical symbols, formulas and equations are a most interesting part of the study of chemistry. To him they present something at once definite and yet mysterious. While further study will teach the limitations of this system of chemical notation and bring the realization that chemical processes can but rarely be represented with absolute correctness, his fingers often itch to use the mystic symbols. And so it comes that we are inclined to use chemical symbols in and out of place; in a measure only, finding excuse therefor in their brevity, the saving of energy or graphite, as when \( \text{C}_2\text{H}_4\text{O} \) is written in place of the word “alcohol.” Not only do some of us use chemical formulas in and out of place, but I have been constrained to feel sorry for the lungs of those who prefer “aitch two oh” to the word “water.” I also have pitied the tongues that were obliged to contort themselves with “ce two aitch six oh” as a substitute for the word “alcohol.”

It therefore is not surprising that in the exploitation of proprietary medicines to the medical profession, chemical formulas have been used to lend respectability to a product and at the same time to awe. This is particularly the case since the attention of the medical profession has been called to the unreliability of the so-called proprietary mixtures. The use of a chemical formula in connection with a proprietary medicine has probably also been made desirable by the prominence which has been given during recent years to the “coal tar synthetics.” While in many instances the unwarranted use of chemical formulas was deliberate and with intent to deceive, in many cases they were used through ignorance, carelessness, or in the belief that a sort of poetic license permitted the use of formulas in connection with proprietary medicines to make them “look good.”

In connection with my work on the Council on Pharmacy and Chemistry of the American Medical Association and the Chemical Laboratory of the Association, I have made it my business to correct, in the interest of chemistry, the abuse of chemical formulas. Unfortunately my efforts in this direction have often been made difficult through the lax use of chemical formulas by those whose knowledge in the matter and whose honesty could not be questioned.

As this abuse of chemical notation to which I have referred is contrary to the best interests of medicine, and as it is liable to discredit pharmacy, I wish to make an appeal to teachers in pharmacy schools to aid in correcting the abuse. Teachers in general, and teachers of chemistry in particular, can aid in this reform in several ways. In the first place they can cease the abuse on their own part in their lectures, their recitations and their writings. In the second place they may insist that their students do not use chemical symbols in a thoughtless, indiscriminate way. They also can aid effectively by recording their objections to the abuse.
As a matter of fact I feel sure that the adoption of the first suggestion will make the second superfluous, for to a large extent the student is but an image of his teacher. However, the student, after the way of the savage who when being civilized begins by adopting all the vices of his white brother, is prone to adopt with a vengeance his teacher's propensity for chemical symbols.

I am well aware that those teachers who make incorrect use of chemical symbols do this as a time-saving expedient. When they write "5 Cc. HCl," or, still worse, say, "I added five Ce Ce aitch Ce El," they realize that, taken literally, their statement means that 5 cubic centimeters of gaseous hydrogen chloride were added. But they argue that, since it is quite evident to them that a watery solution of hydrogen chloride of a certain concentration was used, others also will know what it was intended to express. This may or may not be a correct surmise, but I am convinced that the time saved in this way is more than offset by the inelegance in diction and the harm which is done in suggesting to students slovenliness in the use of chemical symbols.

The second way in which teachers may help to correct the tendency toward incorrect use of chemical symbols is to devote some time to the teaching of how not to use formulas. A little time spent, now and then, in pointing out the incorrect use of chemical symbols has, in my experience, been of much value and interest to students, particularly to those who have obtained their first smattering of chemistry from quiz compends or from a certain class of correspondence schools. In the case of some students, the explanation that formulas can ever be out of place has appeared to them almost as a revelation, and has often aroused added interest in the minds of students. If such illustrations are from life, that is, from the drug-store, they will do much, I am sure, to give the student a more definite understanding of the use and the limitations of chemical formulas.

In the following are given some of the ways in which chemical formulas have been misused in the exploitation of proprietary medicines, as a proof that the abuse of which I have spoken is an actual one. Some of the illustrations given may furnish material for discussion to the teachers who believe in presenting to their classes object lessons taken from life.

Chemical Impossibilities.—Those who are at all familiar with the fraud which has been practiced in connection with the proprietary medicine business know, of course, that many a chemical formula has no more substantial existence than have dreams—and bad dreams at that. It is a frequent occurrence that "inventors" of such formulas are so ignorant even of the elementary principles of chemistry that the very formulas which they use are sufficient evidence that the formulas are humbugs. Thus, a preparation called thialion, shown by the Council on Pharmacy and Chemistry of the American Medical Association to be a mixture con-
sisting chiefly of sodium sulphate and sodium citrate with very small amounts of lithium, furnished a chemical formula,* the impossibility of which a first-year student in chemistry might well be required to know. It would form also an excellent illustration of the laws of combining proportions or valence, and of other elementary principles of chemistry.

Another class of fake formulas which shows the inability of exploiters of a certain class of nostrums to tell an untruth in a plausible way, is that class which fails to "obey" the "law of even atoms." When explaining to students that in carbon compounds the hydrogen atoms of a hydrocarbon should always be an even number, and that, consequently, when these hydrogen atoms are substituted by other atoms of uneven valence, the total atoms having an uneven combining power must consequently be even, interest in this theoretical consideration would probably be increased if it were pointed out that besides Gomberg's "triphenyl-methyl," numerous exceptions to the law may be found in the advertising matter of proprietary products, and that such formulas on entirely theoretical grounds may, with considerable assurance, be put down as humbugs. The following may serve as illustrations of this class of chemical impossibilities:

A cancer cure (Journal, July 27, 1907, p. 345) was said to contain a "new compound derived from a union of hydrocarbons," having the formula C\textsubscript{72}H\textsubscript{17}O\textsubscript{3}. Asked for an opinion as to the probable truthfulness of the claims made for the product, the "Journal of the American Medical Association" said, in part, that "Fortunately for the profession (unfortunately for the promoters) the circular contains such evident earmarks of quack literature that few will be humbugged by it. To a chemist the 'formula' of the supposedly 'new compound derived from a union of hydrocarbons,' is sufficient evidence of the nature of the stuff, for to him C\textsubscript{72}H\textsubscript{17}O\textsubscript{3} spells 'impossible.'"

A preparation called "Pas-Avema" was stated to contain "Somnalgesine," and this compound was variously represented by the formulas C\textsubscript{30}H\textsubscript{28}N\textsubscript{5}O\textsubscript{3}, C\textsubscript{30}H\textsubscript{30}N\textsubscript{5}O\textsubscript{3}, and C\textsubscript{30}H\textsubscript{36}N\textsubscript{2}O\textsubscript{3}. Unfortunately neither of the three formulas are in conformity with the law of even atoms, and may with safety be called humbugs. Examination of the preparation seemed to show that the hypothetical "Somnalgesine" was in reality a mixture of antipyrine and acetanilide.

Possible Compounds in Impossible Mixtures.—Quite frequently when "devising" a chemical formula with which to embellish advertising matter one is selected that is known but which cannot exist in the mixture which is stated to contain it.

As an illustration of this class the ingredients asserted to be present in some of the antiseptic solutions typified by Dobell's solution may be taken.

* "3Li\textsubscript{2}O.NaO.SO\textsubscript{3}.7HO." "Sodio trilithic anhydrosulphate" is given as a synonym. An elaborate graphic or structural formula is also given. (Journal, November 3, 1906, page 1500.)
Unwilling to acknowledge that their preparation differed from that of a horde of others only in name, some promoters have exercised considerable ingenuity in devising ways and means of making it appear that their product contained things not contained in others. So as to avoid detection there has been a tendency to produce imaginary compounds of the actual constituents of the preparations. Thus one of these alkaline antiseptic solutions, shown by analysis to contain carbonate, borate, salicylate, benzoate and other things, has been stated to contain sodium benzosalicylate. While a benzosalicylic acid, formed by interaction of the phenolic hydroxyl of the salicylic acid with the carboxyl of the benzoic acid, has been described (Bloch, Review of Amer. Chem. Research, 1906, p. 230), it would be quite safe to say, from a purely theoretical consideration, that such a combination cannot exist in the solution claimed to contain it. Since the description of benzosalicylic acid specifically states that the acid is readily saponified, it is therefore impossible to retain such a compound in the alkaline solution.

Again, it does not need any chemical examination to show that the composition at one time claimed for Germiletum, one of the many alkaline antiseptic solutions, was impossible. This preparation was stated to be a "slightly alkaline chemical solution of borohydrofluoric acid, borosalicylbenzoic acid, boroglycerin, formaldehyde with menthol, thymol and antiseptic aromatics." The following formula was given:

\[ \text{HBF}_4 + \text{BOH(OCH}_3\text{H}_2\text{COOH)}_2 + \text{BOH(OCH}_3\text{H}_2\text{COOH)}_2 + \text{C}_2\text{H}_5\text{BO}_3 + \text{CH}_2\text{O} + \text{CH}_2\text{O} + \text{C}_10\text{H}_{14}\text{O} + \text{C}_10\text{H}_{20}\text{O} = \text{C}_24\text{H}_{32}\text{N}_2\text{Cl}. \]

Disregarding the unwarranted use of the plus sign, to which reference will be made presently, it needs no great amount of knowledge to say that such of the compounds as are in reality capable of existence alone cannot exist under the conditions obtaining.

Simple Mixtures Presented as Chemical Compounds.—Since a chemical formula lends an air of respectability to a remedy, there has been a decided tendency to represent mixtures or solutions by chemical formulas. Various methods of doing this have been adopted. In some instances, as in the preparation called Germiletum just referred to, the constituents of the preparation have merely been connected by plus signs, thus creating the impression of combination without definitely making the false statement. In other cases the formulas for the several constituents are connected by periods, the sign commonly used to indicate combination between carbon atoms in carbon compounds, and thus more specifically asserting combination between the constituents of the preparation. In many cases the expedient has been adopted of adding the formulas of the several constituents together, thus effectually hiding the nature of the preparation. This is often still further complicated by an error, intentional or accidental, in adding the several formulas together.
In the advertising matter issued for a preparation called "Glycozone" the formula C₆H₁₀O₄ + C₆H₂O₃ usually appears under the name of the article. While this conveys the impression that the preparation is a compound consisting of the constituents indicated in molecular proportion, an analysis (Journal, June 5, 1909, p. 1851) showed it to consist essentially of glycerin to which had been added 5 per cent. glycéric acid.

The preparation known as "Uron" probably belongs to the same class. The exploiters of Uron provided the following formula: LiC₁₅H₁₇N₄O₂. An analysis (Journal, Nov. 3, 1906, p. 1500) showed it to be a mixture of lithium benzoate and hexamethylenamine, and suggests that the formula presents an unsuccessful attempt to add the formulas of the constituents together.

The second method of misrepresenting simple mixtures as definite chemical compounds is the one most commonly employed, chiefly in connection with certain well known organic bodies of established therapeutic efficiency, as in the case of hexamethylenamine, phenacetin, antipyrin, etc. These bodies are weak bases, and form under certain conditions unstable compounds with acids—apparently "by addition." Since a compound of, for instance, hexamethylenamine with some acid, may be sold under a name which will not reveal the presence of the valuable but well known hexamethylenamine, and at a price many times that of its chief constituent, this temptation is great. As these substances really do form combinations, though weak and almost completely hydrolyzed into their constituents when dissolved in water, proof that such mixtures are not definite bodies is not always a simple matter.

One of the host of "fake synthetics," this one of German extraction known as Formurol, is claimed to be hexamethylenamine sodium citrate. According to the formula which the Chemical Factory Falkenberg, in Falkenberg-Grunau, near Berlin, Germany, has supplied, Formurol is a compound produced by the combination of hexamethylenamine and primary sodium citrate in molecular proportions. While theoretically such a body is capable of existence, Zernik, in the Pharmaceutical Institute of the University of Berlin (Arbeiten, a. d. Pharm. Institute d. Univ. Berlin, 1907, vol. 4, p. 46; Journal, vol. 52, p. 1273), demonstrated that Formurol is a mechanical mixture. The method of analysis used by Zernik is generally applicable to products of this kind, and consisted, first, in demonstrating that the hexamethylenamine, sodium and citrate radicals were not present in the relative proportions which were required for the formula, and, second, that by means of solvents which would preclude decomposition, the hexamethylenamine content of the mixture could be dissolved out and thus separated from the sodium citrate.

*Impure Substances Designated by Chemical Formulas.—* Just as some have the slovenly habit of designating the complex mixture, official in the United States Pharmacopœia as "Chlorinated Lime," by the chemical
formula of calcium hypochlorite, its chief constituent, so exploiters of medicines have a tendency to dignify crude, variable or indefinite substances by the formula of the chief or important constituent. Thus a firm offered for sale an article apparently obtained as a side product in the production of turpentine. While the statements of the firm showed that the preparation was a mixture containing chiefly some menthone, the mixture was supplied with a chemical formula, and at first the firm waxed indignant when objection to the misrepresentation involved in the use of the formula was made. In another case a manufacturer who should have known better gave a chemical formula for a mercury compound of nucleic acid and only abandoned it when shown that the product on the market did not contain the amount of mercury required by the formula. While salts of bismuth are notoriously variable and indefinite, proprietary bismuth compounds are almost universally provided with definite chemical formulas. Thus, tannismuth, a compound of bismuth and tannin, has in the past been provided with a chemical formula, although the circular matter which contained its chemical formula also contained the statement that the bismuth content of the preparation varied from 17 to 21 per cent., and gives the needed evidence that the formula was unwarranted.

Simple Solutions Represented as Compounds.—Just as the symbols for hydrogen chloride, hydrogen sulphate and ethyl hydroxide are used to represent the solutions official as hydrochloric acid, sulphuric acid and alcohol, so dealers in medicines have been inclined to represent simple solutions by the formula of the dissolved substance. Thus, a preparation which is now designated as an elixir of chloral alcoholate was at one time marketed in such a way as to give the impression that it was a definite chemical substance.

There is still another way in which teachers can aid in putting a stop to this form of humbuggery in the proprietary medicine business. This would consist in extending their efforts as teachers beyond the four walls of the class room, to the one who perpetrates those formulas. That teachers should so extend their efforts is, I hold, not only their privilege but their duty if they would be real teachers. To be more specific, I believe every teacher might with entire propriety protest to those who are guilty, whenever such abuse comes to their notice. It is a safe prediction to say that, should every teacher take it upon himself to protest by direct communication or through the press against every incorrect and misleading use of chemical formulas coming to his attention, this abuse would become practically obsolete within a short space of time.

The Chair called for discussion on the paper just read. Mr. Hallberg said that while he was not a chemist, and therefore could not appreciate some of the points made by the writer from a chemical point of view, he wanted to refer to the suggestion about the use of chem-
ical titles in proprietary remedies. Commenting upon the author's language: "I am well aware that those teachers who make incorrect use of chemical symbols do this as a time-saving expedient." He said he considered that it was practically necessary to use these shortened chemical symbols in pharmaceutical laboratory work, and he regarded it as proper, legitimate and desirable to do so. In fact, it was practically impossible to conduct the work in the laboratory without the use of such abbreviations. He gave some applications of the convenient use of these symbols. He considered the criticism, as far as it applied to pharmaceutical students, as not well taken, and could see no reason why students should not avail themselves of these shortened forms, where they had not the significance they had in chemical work, in which he could understand the importance of correct statement, in order that the student should not be led into error. He referred to the fact that, in the Journal of the American Medical Association, these abbreviations had been permitted right in connection with the text.

Mr. Kraemer said that when Mr. Motter started to read Mr. Puckner's paper he was very much impressed with the statement regarding the use of abbreviations by students and chemical writers. He did not know of any class of writers that were so careless as to form of expression as the average writer on chemical subjects. He said that it was quite common for authors to use the abbreviations in such a way that they made poor English. Mr. Kraemer said he fully appreciated the importance of saving the time of students, under ordinary circumstances, in the use of these symbols; but he thought it was also very important to call attention to the care that should be exercised in writing papers to see that this was not carried to the extreme so commonly seen in ordinary work.

On motion, the paper was ordered received, to take the usual course.

The Chair next called on Mr. Wilbert to present a paper on the A. M. A. Council of Medical Education, and Mr. Wilbert presented his subject in abstract, the full text of his paper being as follows:

THE COUNCIL ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION.

BY M. I. WILBERT.

In a history of the American Medical Association, written more than half a century ago, Dr. N. S. Davis, the father of that association, says: "Of all the voluntary organizations in our country none is at this time in a position to exert a wider or more permanent influence over the temporal interests of our country than the American Medical Association."

This assertion printed 55 years ago, while a theory at that time, is recognized today to be an accomplished fact, and the force of this assertion is perhaps best illustrated by the many and varied influences that the American Medical Association is wielding in the betterment of conditions
now existing in matters medical. These present day activities are not, however, entirely new and the essential features of the important work now being done by the American Medical Association, particularly that now undertaken by the Council on Medical Education, was foreshadowed in the earlier efforts made by that Association.

The great wave of reform which swept over practically all of the countries of the civilized world some sixty years ago, prompted the better qualified men in the medical profession of America to give heed to the call of the New York State Medical Society for a meeting in New York City, and many, if not all, of the State Medical Societies then existing were represented by delegates.

The primary object of this convention, as set forth by its promoters, was “the adoption of some means to elevate the standard of medical education and advance the dignity and usefulness of the profession.” At the convention, it was pointed out that during the period from 1830 to 1845 the number of medical schools in the United States nearly doubled and that this increase had led to an active rivalry for students and a general lowering of the original requirements. Even in the better class of medical schools 16 weeks of instruction was regarded as the maximum length of the college term while in others the term extended over from 10 to 13 weeks. A compilation of data by one of the earlier Committees on Medical Education of the American Medical Association shows that in the 20 leading medical colleges of the United States, in 1847, the regular term covered from 13 to 16 weeks of lectures by from 3 to 7 professors, and that only 5 of the 20 schools required a practical knowledge of anatomy and in only 6 of the schools was any attempt made to give clinical instruction.

The requirements of the several schools were usually attendance on two courses of lectures or, in the event that the candidate had been in practice for more than 2 years, one course of lectures was sufficient.

Some idea of the general status of the practice of medicine in this country is evidenced by the report of a committee on the status of medical practitioners in the state of Virginia where, in 1847, there were a total of 972 medical practitioners 678 of whom had received diplomas from medical schools while 249 practiced without authority.

The need for correcting existing abuses in connection with medical schools and the practice of medicine generally was generally recognized. Appreciating the difficulties that would be encountered the American Medical Association Committee on Medical Education, for 1851, points out that: “One of the means of removing the abuses which exist in our profession is to expose and attack them. While this should be done thoroughly and fearlessly it should also be done with a candid and conservative spirit. Any exposure of these abuses which is made with a wrong spirit does harm.”
One of the really serious problems of that day was found to be the limited qualifications of the greater number of even the graduates in medicine. Thus it was shown that of the 12,400 graduates from eight of the leading colleges but 934, only 1 in 13, had taken up the practice of medicine while 3,211, or 1 in 3, had entered the clerical profession.

The enthusiasm prevailing among many of the members of the medical profession caused at least some of the then existing schools to extend their course quite appreciably. Thus in 1851 Dr. Geo. B. Wood announced in his introductory lecture that the University of Pennsylvania had extended its regular course to six-months.

For several reasons the earlier attempts of the American Medical Association to improve medical education failed to have a permanent influence and Geo. B. Wood, writing in 1860, says: "After the first enthusiasm of the profession under the influence which gave rise to the American Medical Association had subsided, it became obvious that our school would be unable to sustain itself in the degree of expansion which it first attempted and that the six-months course must be abandoned."

For many years the American Medical Association was practically dominated by men interested in the development of proprietary medical schools, so that for a long period of time little or no progress was made. Less than two decades since, Dr. H. C. Wood, in an address to the students in the Philadelphia College of Pharmacy, asserted that: "Medicine has run riot in these United States. There is no civilized country, or even a semi-barbarous republic of South America in which the profession of medicine is not regulated by law, but here every man ignorant or learned in the profession has been allowed to put out his sign."

"Almost any half dozen doctors, may, if they wish, establish a medical school, at almost any cross-road and each new medical school is a new competitor and leads to the cheapening of the degree...and so the process has gone on until diplomas of American Medical Schools have come to be a laughing stock."

This was the general condition existing in the early nineties when a number of the more able practitioners interested themselves in renewed efforts to raise the standards of medical education and thus give to American medicine a degree of respectability that had never been claimed for it before.

The organization of the medical department of Johns Hopkins University was undoubtedly one of the more important factors in the development of this movement, and the originators of that school will ever hold a prominent place in the history of American medicine for having established a new standard for medical education in this country.

Another and perhaps the most important factor in this evolution was the reorganization of the American Medical Association in a way to effectually rid it of the domination of men interested in proprietary medical schools.
The several steps in the evolution of medical education in the United States, while interesting, are not creditable to the ideals or motives of the founders of these institutions. Many of the proprietary schools were originated by men who were themselves not graduates in medicine. At a later period the leading schools at least saw the error of their way and made some attempt to improve; this failing, they continued as best they could, and finally, through the initiative of a few strong men, a limited number of schools introduced higher requirements and, with the assistance of other agencies, are now compelling the more backward schools to improve their curriculum or to close their doors.

The Council on Medical Education, the leading spirit in this present-day reform movement, was instituted in 1904, and its functions are defined as:

1. To make an annual report to the House of Delegates on the existing conditions of medical education in the United States.
2. To make suggestion as to the means and methods by which the American Medical Association may best influence favorably medical education.
3. To act as the agent of the American Medical Association (under instructions from the House of Delegates) in its efforts to elevate medical education.

At the first Annual Conference of the Council on Medical Education of the American Medical Association, held in Chicago, April 20, 1905, it was shown that some of the best and all of the worst medical schools in the world are to be found in the United States.

The proprietary medical school, in the widest application of that term, was early recognized as being the greatest bar to progress, and from the beginning attempts have been made to bring about a closer affiliation between medical schools and recognized universities.

In all European countries medical schools constitute the medical faculties of established universities or are directly controlled by the university. In our country, however, the medical school has usually been developed as an independent organization, or when connected with an established university the affiliation was in name rather than in fact. Largely because of this latitude in our established practices we find that of the 309 medical colleges in all countries, the United States has 144, or 47 per cent., while the 30 other nations altogether have only 165, or 53 per cent.

In addition to the Council on Medical Education, a number of agencies are now at work which tend to elevate medical education. The great universities with medical departments are endeavoring to advance their requirements to a point at least equal to the requirements of similar institutions abroad. The examining boards in many States have done much, the Association of American Medical Colleges has been a factor of importance, and outside influences like the Carnegie foundation for the advance-
ment of teaching are in a position to and do wield a beneficent influence on the general trend of this movement. All of this influence, however, would avail but little were it not for the widespread publicity that has been given to the several efforts by the Journal of the American Medical Association and the fact that through the Council on Medical Education the efforts of these several agencies have been correlated and enlarged upon.

The several steps in the evolution of medical education are perhaps best illustrated by the compilations of results published annually in the Journal of the American Medical Association. While I should like to present to you a more comprehensive study of the several annual reports, I will content myself with calling your attention to but one.

The report for 1908 shows that the total number of medical students (matriculants) in the United States for the year ending June 30, 1909, was 22,145, the lowest number since the Journal began compiling these statistics in 1900 and a decrease of 2,131 below 1907. From the tables given it appears that the maximum attendance was reached in 1904 with 28,142.

The total number of graduates amounted to 4,442, the lowest number in a decade; the maximum 5,747 was reached in 1903.

Up to the present time the Council on Medical Education has succeeded in:

1. Reducing the total number of medical colleges.
2. Compelling existing colleges to raise their entrance requirements, lengthen their course and increase their facilities.
3. Publishing facts in connection with existing conditions which have served to bring about improvements in State medical-practice acts and increased requirements on the part of State licensing boards.

The work that has been accomplished by the Council on Medical Education of the American Medical Association amply illustrates what can be done by united effort on the part of the better class of men engaged in any one profession or calling.

The recognition that has been accorded to American medicine during recent years, and the outside influences that are now at work to still further improve the status of medicine in these United States should spur us pharmacists on to even greater efforts than we have ever made in the past, to establish for ourselves a status similar to that now enjoyed by medical men.

The American Medical Association has demonstrated that remarkable changes can be brought about in a comparatively short space of time. The publicity that has been and is now being given to the efforts of the various agencies engaged in raising the standards of medical education is sure to attract attention and, unless we pharmacists ourselves take the initiative, outside influence will surely compel reforms in the teaching as well as the practice of pharmacy that will be equally far-reaching.
The Chair invited discussion on the paper just read.

Mr. Taylor said he felt deeply on the proposition just proposed, and wanted to call the attention of this Association to some of its fallacies. In the first place, he said, the Medical Council certainly had no effect whatever in the State of New York. In the second place we believed it did not have any effect throughout the United States. In the third place, he could not conceive of any right to prevent the American Pharmaceutical Association from tying up with the larger organization. He was prepared to debate this matter at length, but conditions prevented any discussion at this time. Mr. Taylor did, however, make some remarks upon the situation in New York, and claimed that what had been accomplished there was not through the Council of Medical Education, or the American Medical Association, but it was the medical houses and medical colleges that did the work.

Mr. Kraemer did not agree with Mr. Taylor. He thought this Association was indebted to the American Medical Association for what they had done. While he did not think any one desired to give any one association undue credit, he had been very much interested in the paper that Mr. Wilbert had presented, and whether this work was to be done through some special organization, as at present, or was to come through this Section, he could not help but believe that all these things were tending to the uplift now in progress. The outside organization, as well as the work that had been done here, had certainly had an uplifting influence. He moved that the paper be accepted and referred to the Committee on Publication.

Mr. Cliffe seconded this motion. He said he thought Mr. Taylor had taken an erroneous view of the attitude of this Section, and the work that had been done here. The papers, he said, were presented by invitation, and were presented as a rule to this body—to this forum—through which these ideas could be disseminated to the pharmacists of the country at large. It did not necessarily involve the proposition that the Section or Association agreed with the conclusions of the writers. They were simply presented for consideration by the pharmacists of the country of the germ of thought advanced which eventually brought good through discussion; and whether that discussion occurred subsequently to the meeting or at the time of the meeting was really an immaterial matter.

The Chair thereupon put the vote on the motion to receive the paper and refer it to the Publication Committee, and it carried.

The Chair next called for a paper on the subject of "Pharmaceutical Education in Germany," by H. P. Taylor.

After an explanation of the circumstances under which the paper was written and presented, Mr. Taylor asked the privilege of withdrawing it without reading, as he did not consider that the Section, now at the close of its third session, and with practically all of its members gone, was a "proper forum of debate."
The Chair stated that Mr. Taylor's wishes in this matter would be acceded to, and the paper would be returned to him.

The Chair said it was unfortunate that the Section had reached a very important part of its program, with practically all its members gone, but disclaimed any responsibility for the situation, as the regular order of business had been interrupted yesterday by having to give way to an adjourned session of the general Association. He said the next matter on the program was the report of the Committee on Pharmaceutical Syllabus, and asked Mr. Taylor if he had any report to make.

Mr. Taylor said he was Secretary of the committee, but the Chairman was to have presented the report, and the President of the Association was to have been here to speak on one subject and Mr. Engstrom on another, and both were absent.

And so the matter was passed.

The Chair next called for a paper by Mr. Eberle, of Texas, upon the subject of "Suggestive Methods in Teaching Pharmacy"—a paper not on the program; and suggested that the paper be read by title, in the absence of the writer.

The motion was seconded by Mr. Roe, of Indiana, and carried.

The text of said paper here follows:

SUGGESTIVE METHODS IN TEACHING PHARMACY.

BY E. G. EBERLE.

The paper here presented is at the request of the Chairman, who has asked me to explain my method of communicating information to students. I call it a plan of leading the student to think and obtain the knowledge for himself. The information is already there; all that is necessary is to aid him in discovering and after that it is for him to make use of what he has discerned. My explanation is very superficial and brief, but you will read between the lines. Nor do I think I am presenting anything new, but having been away from the fountain-heads of pharmaceutical knowledge and source of supply since my school days, I developed my own course of instruction, with the text-books of my superiors for a guide.

The purpose of education is to train the mind, to qualify by instruction, and this is best and most effectively accomplished by inducing thought, consideration and investigation. Lack of this is frequently evident in book learning, which so very often simply gives definition. The student who seeks to know the reason why will attain better results than the apparently brighter one who learns without analysis or synthesis. The writer in teaching students dwells more on the work done in accomplishing results than in the means employed or the results themselves, deeming the why and wherefore more essential and valuable because it teaches general application of the principles involved. The inference, for instance, that heat acts as a clarifying agent in fluids containing albumen is incomplete without
the further explanation that albumen is coagulated by heat; that this caused the fluid to be more or less opaque or cloudy and, now, that it through the action of heat has been thrown out of solution, the fluid is transparent. This with experimentation shows the application of the method, necessitating of course further explanation when this may and may not be used and why.

In explaining general principles involved in preparing, comminuting and extracting drugs, each step has interest when simply explained with practical work. Take comminution; it is an easy matter to show why a certain means to accomplish this end is best, and why the method employed in powdering another drug is not applicable, and when exemplified impresses the student, it promotes thought and thereby proper application. It is well enough to say that in a No. 40 powder a certain percentage only shall pass through a sieve of a finer mesh, but, unless the objections are demonstrated, it is not thoroughly made clear to the student's mind. He should also be shown that force should not be used in sifting, for thereby larger pieces come through; that to throw these away augments the strength of the drug. To take an assay method, tincture of opium for example:

The first step in the process is to remove the alcohol and the next to obtain an aqueous solution in which matter insoluble in water is thrown out. The reason for keeping the washings separate and evaporating this first to a small volume is to avoid unnecessary heating of the concentrated solution. This solution naturally contains other alkaloids of opium than morphine. The alcohol is added to prevent precipitation of the coloring matter which would contaminate the separated morphine; the ether removes codeine and other ether-soluble alkaloids, ammonia is now added to free morphine as alkaloid; the thorough shaking for ten minutes is to aid in this separation. The mixture is allowed to stand for at least six hours to insure complete separation; it should, however, not stand longer than twenty-four hours, for by that time other matter will begin precipitating. The next step is to remove the liquid portion containing other alkaloids than morphine by filtration. The filters are moistened with ether so as to facilitate this. The Pharmacopæia prescribes a double filter, others prefer a single filter of hardened paper from which the crystals of morphine can easily be removed. Those of the Pharmacopæia are plain, not folded, for like reason.

The crystals of morphine are washed with alcohol saturated with morphine; this is to remove coloring and other foreign matter, the alcohol solution being saturated will no longer dissolve morphine. A solution may be saturated with one substance and still be a solvent for others and this is the case here, but if the alcoholic solution was not washed out, on evaporation of the alcohol its morphine content would be left within the filter, therefore ether is again used to wash this out. The crystals are then dried at a temperature not exceeding 60° C.; this is to prevent loss
of the water of crystallization. Then the crystals are weighed on a watch glass. In this condition there are still some impurities left with the morphine and these are removed in the next step of the process, dissolving the morphine in lime water. This leaves the impurities in the filter, which being dried and weighed and weight deducted from that previously obtained gives us the amount of morphine in 100 Cc. There is opportunity for error in the counterpoising of filters, as one is apt to absorb more of the calcium hydroxide than the other, also more or less of it is converted into calcium carbonate.

The student studies the different drugs, method of collecting, preparing, etc., but it is a good idea in each class of preparations to pick out one or two and tell its story from the beginning; thus of opium, to begin with the seed, tell of the growth up to the collection of the juice, of its home and those engaged in raising and collecting, continuing until the lump of the opium is in the hands of the pharmacist ready for being made into preparations. This is very much after the “kindergarten” presentation and may not be in conformity with more advanced teaching. It is impractical to devote this much time to many preparations; still even one preparation considered in this manner refreshes the mind and perhaps impresses the student better than when the subject was more thoroughly explained at an earlier period.

These brief examples will suffice for explaining my plan of teaching the juniors, with whom I devote more time and to whom I give most attention; for after laying a good foundation and leading them to think rather than to commit, to analyze and dissect and thereby discover in preference to accepting statements simply because they are facts and have been stated by some one who knows, their studies of the succeeding year are much more readily assimilated and applied.

The Chair now called for the installation of the officers of the Section as the final order of business, and requested Mr. Peter Jensen, of Tacoma, to introduce the Chairman-elect, Mr. Charles W. Johnson, of Seattle.

Mr. Jensen performed the duty assigned him in a few graceful words of compliment to Mr. Johnson for the valuable work he had done, and said it had been greatly appreciated among his people. It had been a great and good work, as those who knew of it could testify. He said the State of Washington was proud of Mr. Johnson, and that he had not only “made good” among his people in the West, but his name stood among the greatest in the country in his chosen profession.

Mr. Johnson said it was unnecessary for him to make any extended remarks at this time, and he only wanted to say to the members that the Committee could only be successful at the next meeting by a thorough and earnest spirit of fraternity and interest in the cause of education and legislation throughout the country, and he thought he voiced the sentiment
of the Committee when he said that they earnestly solicited the support of the members.

Mr. Johnson then took the chair.

The Chair stated that as the newly-elected Secretary was absent, his installation would have to be dispensed with.

Mr. Kraemer said this had been an unusual year in the history of the Association, and that there had been so many papers presented, and the work had been so difficult, that he felt it was proper to move a vote of thanks to the retiring officers for their ceaseless efforts to make this meeting a success.

The motion was seconded by Mr. Hays and others and carried unanimously.

On motion of Mr. Roe, the Section then adjourned.

REPORT OF COMMITTEE ON DRUG REFORM OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.*

The importance of the National Food and Drugs Law of 1906 need not be impressed on pharmaceutical men, nor the benefit already realized from it and from the numerous State Laws that have been modeled largely upon it. Yet every pharmacist knows that adulteration has by no means been eliminated since these laws have been enforced. It might seem to many that these laws have operated more to expose the extent of adulteration than perceptibly to check it.

Pharmacists do not need, moreover, to be reminded of the danger to their profession from drug adulteration. The increasing distrust of drug-store preparations, on the part both of physicians and of the general public, and the resultant tendency toward "drug nihilism," have been generally noted by writers in the different pharmaceutical journals.

The first object of the American Pharmaceutical Association is, according to its constitution, "To improve and regulate the drug market by preventing the importation of inferior adulterated drugs, and by detecting and exposing home adulterations."

In accordance with this object President Rusby, in October, 1909, appointed the Committee on Drug Reform. A former committee, although it bore the same name, seems to have been designed primarily to co-operate with a similar committee of the American Medical Association. The present committee, having a somewhat different phase of work, has therefore been compelled to begin anew.

In view of the short interim between the meetings of the association, it was evident at once to the committee that few immediate, tangible results could be accomplished. To this lack of time was added the difficulty of determining the exact function of the committee. This function is not, of course, executive. In the opinion of the president of the association and of the members of the committee, its duty lies rather in awakening public interest in drug laws, and in influencing the legislation and enforcement of them by indicating at what reform must be directed and by suggesting, as far as possible, how that reform may be accomplished.

According to this conception of its duty, the committee, in February, issued 75 circulars, requesting opinions concerning the means necessary to accomplish four things:

1. More thorough restriction of the importation of impure drugs at all United States ports.

* This report was read by title at the second general session of the 1910 meeting, but failed to receive final action.—The Gen'l Sec'y.
2. Improvement in the inspection of intrastate commerce in drugs.
3. Uniformity and efficiency in State inspection and supervision.

The circular also asked for opinions on the proposed changes in the substandard clause of the Federal Act, (Sec. 7) which would, if adopted, require the label of any substandard drug to state not only its absolute standard, but also the relation of that standard to that of the U. S. P.

The correspondence elicited by this circular has been a decided help to the committee, and the interest manifested by a considerable number of pharmaceutical journals, schools, and other important institutions will undoubtedly further the progress of reform.

The opinion seems to be prevalent that inspection of drugs at the ports of this country should be made more stringent. In the first place, not all ports of drug entry are under inspection, and in the second, at those ports which are, the final decision on the question of admission or rejection of drugs, after they have been analyzed by experts, rests with persons who know almost nothing of them. Moreover, responsibility for the supervision of drug importation is divided between different divisions of the Departments of the Treasury and of Agriculture. If this responsibility can be made more definite by fixing it on a single department, the condemnation of undesirable drugs will be much more certain.

President Rusby has already called attention to the importation of materials used in the adulteration of drugs. Some of those materials, since they are also used for legitimate purposes, cannot well be excluded. We may, however, exclude those used wholly for adulteration, such as ground olive pits and coconut shells, which are, under the present laws, shipped boldly into this country under their real names. In the opinion of eminent legal authority consulted by this committee, the exclusion of such materials is possible by legislation.

Mr. M. I. Wilbert, whose connection with the administration of the Federal Drug Law is well known, writes that more rigid inspection of Drug importation can be realized "only by education so as to bring about a demand for such inspection."

Interstate supervision naturally presents a more difficult and troublesome problem to the federal officials than does the work at the ports of entry. There can be no doubt that this interstate drug inspection, considering the funds and the force of men available for the work, is remarkably efficient. Yet there is no doubt, on the other hand, that inspection never reaches a large part of interstate drug traffic, and that shipments of adulterated drugs are, at present, being safely made. Such shipments will continue to be made until the federal government allows this interstate supervision a much larger appropriation, for efficiency can be obtained only with a larger and better paid service.

State drug laws differ to such an extent that only general suggestions applicable in all states, can be made here. Perhaps, at present, more attention should be devoted to law enforcement than to legislation, for in drug reform, as in every other reform, there is a lamentable tendency to regard the work as accomplished by the mere passing of a bill through the legislature.

More stringent administration of the State drug laws now existing can be obtained by impressing the importance of such laws on the public and the responsibility involved in their enforcement on the State Officials. This work can be achieved by a future drug reform committee with at least one member from each State Association.

Another important change which the committee wishes emphatically to recommend is the separation of the duty of the enforcement of drug laws from the work of departments whose principal function is entirely foreign to the control of drug traffic. Prof. E. V. Howell, of this committee, writes that in North Carolina "The Food and Drugs Law is in the hands of the Department of Agriculture, which is maintained by a tax on every ton of guano. Thus the farmers support the department. So far the department
has done good work on fertilizers, stock foods, poultry powders, and plant foods, but nothing for pure Drugs for sick people." The enforcement of drug laws is worthy of a distinct division of an independent State Board of Health, or Board of Pharmacy.

Enforcement of the drug laws can be much improved by co-operation between the State and the Federal Laboratories and inspectors. President Rusby has cited a case which illustrates the need for this co-operation. Dr. L. F. Kebler, Chief Chemist of United States Drug Analyses, on discovering material used for adulteration in a Hoboken drug house, was openly defied by the proprietors, since the material was not under federal jurisdiction. The proprietors boldly admitted that the material in question was to be used in drug adulteration. In such a case as this, co-operation with the state officials would have brought about an inspection by officers whose authority could not have been defied.

Mr. Wilbert, referred to above, writes concerning co-operation: "Unless some one is willing to agitate this question quite thoroughly each individual drug inspector will be a rule unto himself and the several state laws will continue to be, as they are at present, enforced without regard to the requirements made in any other state."

Further efficiency in State enforcement can be gained by more uniformity in drug standards. As long as scores of standards exist for every drug no stringent administration of drug laws can be expected. Recent State legislation has shown an encouraging tendency to adopt the National Standards, either entirely or with very few exceptions. In twenty-nine States the federal clauses defining adulteration and misbranding of drugs are thus followed verbatim or in substance. In other words, the laws of almost two-thirds of the states resemble the National Act in these important provisions. Yet the remaining States in which these provisions are dissimilar include some of the most important ones, such as New York, Massachusetts, Michigan and Illinois.

Uniformity of standards might be promoted by the efforts of such a committee as has already been suggested, with at least one member from each State in the Union.

A special recommendation which the committee desires to make, concerns the lack of inspection of drugs used by the so-called "dispensing physicians," who are especially numerous in the western part of this country. This lack of inspection of physicians' drug supplies, leaves an unwarrantable loophole for the distribution of adulterated drugs. As a general rule, moreover, dispensing physicians are not especially careful in buying their drugs, many of them being governed by price alone. It is therefore desirable that the State inspectors should be given the right to examine drugs in the possession of physicians and to prosecute the manufacturers of any such drugs who shall fail to comply with the standards which are provided for druggists. Professor J. H. Beal in an article on "The Quality of Drugs Dispensed by Some Physicians,"* exposes this channel for the distribution of adulterated drugs.

During the past year, beginning March, 1909, 1127 samples of drugs have been examined in the Kansas Drug Laboratory and reported in accordance with the Kansas Law to the State Board of Health. Three hundred and eighty-two of these samples were Tinctures of Iodine, 50 per cent. of which were found below standard; 134 were Essence of Peppermint, 65 per cent. below standard; 145 were Spirit of Camphor, 28 per cent. below standard; 55 were Tincture of Ginger, 31 per cent. below standard. These 716 samples were preparations which the druggist had made, or should have made, himself. The remainder was composed of 50 samples of patents and 344 miscellaneous drugs. Among the patents were several hair tonics found to contain Wood Alcohol, while other patents were misbranded. The percentage of adulteration and misbranding is even greater among the miscellaneous drugs than among those mentioned in their respective classes. It should be noted in this connection that inspectors are instructed to

*See Drug Cir. '08, : 367.
collect only suspicious samples and therefore the above percentages of adulteration indicate only the average purity of suspicious drug products. But this showing is sufficient to convince anyone of the importance of intrastate drug reform, and especially of that phase of it, which applies to individual druggists. As a California correspondent expressed it, "we will have to reform the druggist before we can reform the drugs." Similar analyses have doubtless been completed in other states. The Kansas analyses have been cited because the work in that State is more familiar to the chairman. The committee is satisfied, however, that unless work of a similar nature is carried on in every state, the ideal of drug reform will be very far from realized.

Dr. Albert Schneider suggests that this committee, of which he is a member, consider the following matters:

1. The efficiency of macroscopical and microscopical inspection in determining the purity of crude and powdered vegetable drugs.
2. The efficiency of chemical examination of vegetable drugs.
3. The determination of a practical standard of purity for the more important vegetable drugs.
4. The determination of an age limit for vegetable drugs.
5. The determination of the exact commercial source of the most important drugs.

While the investigation of these questions is not necessarily comprised in the work of this committee, the results of such investigation would be of great value in the work of drug reform.

Dr. Schneider and Prof. Howell have both emphasized the need for governmental encouragement of the propagation of drug plants, especially through experimentation. Dr. Schneider, for the reason that the United States would, by increased domestic production, be made independent of the fluctuations and variations of foreign supply, and Prof. Howell for the reason that the present methods of gathering the wild plants is rapidly bringing many species to extinction.

Letters received by this committee indicate that some of the members of the association wish to restrict the advertising of medicines by persons not qualified to manufacture and dispense them. The only suggestion for such restriction which the committee is able to make is that this restriction might be provided by amendment of the State Pharmacy Laws—the same laws which compel physicians and pharmacists to prove their qualifications. Legal opinion sought in regard to such an amendment has been favorable to it. More effective still would be proper restriction of the use of the U. S. mail.

Prof. Howell has collected advertisements of cancer, morphine, cocaine, and whiskey cures, and has calculated the percentages of newspaper space devoted to them. This material, it is hoped, will be ready for submission at the meeting of the association.

J. L. Conant, Jr., Secretary of the Idaho State Board of Health, has suggested that the committee draft a model drug law for adoption by every State in the union. This work would probably encroach on the duties of the committee on National and State Legislation. At any rate the association should make some provision for this work, by instructing one or more committees to carry it out, for the enactment of uniform drug laws is of almost as much importance as the co-operation of the officials provided for their execution.

While the committee on Drug Reform has not drafted a model law, it wishes to call attention to the analysis of the Federal Food and Drugs Act by a committee of the Maryland State Board of Health. The Food and Drugs Bill drawn up by this Maryland committee for submission to the legislature of that State follows the National Act except for certain alterations. One of these is the provision that substandard drugs, in addition to the statement of their own standard, must bear the further statement that they are not intended for medicinal use, and are not to be used in the filling or compounding of any prescription or order of any registered physician, dentist, or veterinari-
In the opinion of the Maryland committee, "The use of substandard drugs for medicinal purposes is unnecessary, dangerous, and contrary to public policy."

A recent change in the Pennsylvania law in regard to substandard drugs, allows a deviation, if stated on label, in all drugs except Opium, Iodine, Peppermint, Camphor, Ginger, and Ethyl Nitrite. These six drugs must conform strictly to the U. S. P. Standard (Pa. Act of May, 1909, Section 3).

The Maryland committee also struck out the guaranty clause of the National Act. They are of the opinion that it would emasculate the entire bill, since the State, outside its limits, would have no jurisdiction over manufacturers or wholesalers by whom most of the guaranties to Maryland jobbers and wholesalers would be given. The committee states: "The Government of the United States grants exemption only to the jobber and retailer when its jurisdiction can reach the manufacturers: the State should do likewise." The committee finally decides, however, that no guaranty at all should be provided for by the State, since exemption in the case of drugs manufactured within the State, would discriminate against those persons who might prefer, or be forced, to obtain drugs from without.

This committee believes that the association can aid the work of law enforcement by creating a separate division of the scientific section to consist of all those who are especially interested in analyses with reference to the different drug laws—a division which would convene on a special day each year to determine and unify processes and standards and to compare results. It would, in short, be a clearing house for drug inspectors and analysts. At the last meeting of the American Chemical Society, a special section was formed which includes drug analysts. It seems to this committee that our own association is a more natural center for such work.

The present members are of the opinion that the Committee on Drug Reform should be made a standing one. The absurdity of trying to accomplish actual reform in a few months is evident. Practical results can be obtained only by a permanent committee.

ALBERT SCHNEIDER, San Francisco, Cal.
E. V. HOWELL, Chapel Hill, N. C.
L. E. SAYRE, Lawrence, Kan., Chairman.
MINUTES
OF THE
SECTION ON SCIENTIFIC PAPERS.

FIRST SESSION—TUESDAY AFTERNOON, MAY 3, 1910.

The Section was called to order at 3:15 p.m. by Chairman M. I. Wilbert, of Washington City.

The Chair stated that quite a long program had been prepared, and in addition to the numerous list of papers appearing on the program, the section had before it eight other papers. He stated that when the committee started out to compile the program, the contributors were told that an effort would be made to get the section to adhere to the program, and unless the majority of the members objected, that rule would be followed. Where contributors were not present, their papers would be read by title only, and contributors not on the program would have to bide their time, and the Section would consider as many of their papers as possible after the regular program was finished.

The chair then called on Mr. W. O. Richtmann, of Florida, Associate on the Committee, to take the chair while he read his address, which he then proceeded to present as follows:

CHAIRMAN'S ADDRESS.

Precedent has established for the Chairman of this Section the privilege to present an address on matters that he may deem to be timely, thus giving him an opportunity to outline or suggest lines of investigation that, in his opinion, would prove to be fertile fields for work.

In taking advantage of this opportunity, I desire to present to you some personal opinions and suggestions on the fields of inquiry and of policy that I consider to be opportune, if not imperative, should we desire to leave for future generations of pharmacists a heritage that they can feel proud of and an example that they may well choose to follow.

THE PHARMACIST AND THE PUBLIC HEALTH.

During recent years, we, the people of this American Republic, have been awakened to the desirability of conserving our natural resources so as to avoid, if possible, the continuance of the all but criminal waste that has been going on in nearly every section of our country.
As a direct outcome of the resulting agitation it has been conclusively shown that the loss of human energy, through morbidity and mortality by preventable diseases, constitutes by far the greatest waste of our present resources. Even when measured by the popular, utilitarian standard of dollars and cents, the money value of this loss far exceeds that of all other known losses combined.

Physicians individually and collectively have devoted considerable thought, time and money to the study of the problems that are involved and for upwards of half a century they have been agitating, more or less effectively, for the adoption of measures designed to prevent the spread of communicable diseases, and thus promote the well-being and the longevity of human kind.

It would be altogether too far-reaching to review at length the splendid work, in the line of the prevention of communicable diseases that has been accomplished during the past half-century or more. The knowledge that has been gained concerning tuberculosis, yellow fever, enteric fever, malaria, bubonic plague and cholera, not to mention trypanosomiasis, ankylostomiasis and numerous other communicable diseases, has enabled medical men to indicate clearly the precautions that are necessary to prevent the unnecessary spread of these diseases, or to eradicate them entirely. How really efficient these sanitary measures are in practice has been well demonstrated on the Isthmus of Panama where the Sanitary Department of the Isthmian Canal Commission has practically eliminated tropical diseases from a reputed pest-ridden region.

Even the non-medical social economist realizes that disease and premature death constitute important inhibiting factors to human progress, and that the nation that can rid itself of these impediments most successfully is destined to lead the world in other respects.

While medical men have taken an active part in laying the foundation for future activities in sanitary science and preventive medicine, we, as pharmacists, have neglected our opportunities, and, as a class, at least, have done little more than occasionally endeavor to utilize the result of published work in the exploitation of proprietary medicines of questionable value or use.

This perversion of scientific work on the part of the followers of our craft is perhaps one of the most serious charges that have been made against pharmacy as a calling. The accusations that have been laid at our doors in this connection appear all the more justified when we remember that our present-day knowledge of medicines and their uses is as yet woefully imperfect, and that, as pharmacists, we have been particularly backward in recognizing the limitations of medicines, and the possible harm that may result from their abuse. Many of us are as yet unwilling to admit that the science of the chemist and the art of the physician are far indeed from having reached that state of perfection where the needs of the animal organism can readily be determined or the effects of any given substance on the pathologic condition foretold with any degree of accuracy.

While it is true that the art of synthesis may and probably will add valuable medicaments to our store of remedial agents, it is a grave question indeed whether the results so far achieved are not to be deplored rather than lauded, whether the lives unduly shortened do not actually outnumber the lives that have been prolonged by the all too liberal use of the products of the tar barrel.

In how far we as pharmacists are to be held responsible for the harm that has been and is being done by these remedies is not to be determined at the present time. Certain it is that our indifference to ultimate results is largely responsible for many of the present as well as past abuses in connection with so-called synthetic remedies and many of the other physiologically active drug products.

As a class, we have become so indifferent to the every-day use of drugs that we do not always fully appreciate the possibility that even the continued use of saline cathartics, or any one of the widely advertised purgative mineral waters, may do harm directly, by
further developing a tendency to spastic constipation, and, indirectly, by masking for a time symptoms that may prove to be the early indications of more than serious disorder.

It has been asserted, and with much evidence of truth, that, as a class, we pharmacists are altogether too numerous and that our very numeroseness is a menace to the public health. To the impartial observer existing conditions in the drug business are indeed disheartening, and particularly so when he compares the sum total of the persons engaged in the various lines of the drug business with the total membership of the societies and associations that are devoted to the development of the sciences relating to pharmacy. Nor will his disappointment be modified by remembering that apart from physicians in active practice, no class of men could exert a more beneficent influence on the development of public hearth work than the practical pharmacists who supply the medicines used in the community and who should, at least, safeguard their abuse.

Our failure to take the place that we really should, in the development of the sciences relating to medicine, is due to a combination of a number of pernicious influences that might readily be summed up by the one word, commercialism. As a class we have been ground between the upper and nether millstones of expediency and necessity; we have been misled by false prophets and have in turn refused to consult with our fellow-practitioners for fear that they were desirous of utilizing us for the promotion of their individual schemes or purposes. As we have increased in number we have decreased in weight or influence, and altogether we appear to have too much in common with that class of medical practitioners whose mentality is described by Dr. Osler as being suggestive of that little dried up miniature of humanity, the prematurely senile infant whose tabetic marasmus has added old age to infancy.

**LOST OPPORTUNITIES.**

Five years ago the then chairman of this section, Mr. E. H. Gane, presented an able review of the needs of American pharmacy and the desirability of adopting a more aggressive attitude in dealing with pharmaceutical problems. He pointed out that one by one the legitimate scientific sidelines of pharmacy have passed into other hands, largely, perhaps, through lack of co-operation on the part of the various agencies that should have been of assistance in maintaining the professional status of the pharmacist.

At that time he, very properly, pointed out that the pharmacist should lead in knowledge of drugs, their behavior and the best methods of presentation. It should be his part to make practical applications of the results of scientific research, to aid in replacing crude drugs by definite principles and to urge the abandonment of unscientific and inert products. He warned against the further usurpation of the functions of the pharmacist by official chemists and dairy commissioners and called attention to the formation of the then newly organized Council on Pharmacy and Chemistry of the American Medical Association. He pointed out that the work that was being undertaken by this Council should have been inaugurated by the American Pharmaceutical Association and urged that the latter association make immediate provision for co-operating in the work of the Council on Pharmacy and Chemistry of the American Medical Association.

The warnings voiced by Mr. Gane five years ago were practically disregarded, and even the more significant admonitions reflected by the enactment of Federal and State pure food and drug laws have been practically ignored by the rank and file of pharmacists not directly engaged in doing an interstate business.

Opportunities once lost can never be regained, and our failure to take advantage of the suggestions offered by Mr. Gane five years ago lost to pharmacy the opportunity of taking an active part in a movement that has already done much to rid medicine of at least some of the deception and fraud practiced knowingly or in ignorance by men who claim affiliation with our ranks.
THE COMING REVISION OF THE U. S. P.

Just at the present time we are confronted with differences of opinion regarding the scope and content of the one book that has been the direct or the indirect cause of much of the proprietary medicine abuse under which the professions of medicine and pharmacy are now suffering. This book, the Pharmacopoeia of the United States of America, is about to be revised and the U. S. P. Convention, which is to assemble in the city of Washington on May 10, is to decide definitely on the policies that are to be followed in revising it.

It goes without saying that unless the coming revision of the U. S. P. can be brought in line to meet the requirements of the hour, the U. S. P. IX will be as far from proving to be a panacea for our proprietary medicine ills as was the U. S. P. V. or any one of its successors.

Much of our time at this meeting will be devoted to the consideration of problems bearing more or less directly on the possible development of the U. S. P. along lines that will tend to make it more acceptable, as a standard for the identity and purity of the articles it describes, as a dependable guide in making the preparations enumerated in its pages, as a reliable basis for the teaching of materia medica in medical schools and as an authoritative source for medical prescribing by competent and sane physicians.

The Pharmacopoeia could, and in my opinion should, be an important factor in advancing rational drug therapy, and thus assist in eliminating the inevitable sequence of the ignorant or uncertain use of drugs which leads to therapeutic nihilism, on the one hand, and hopeless drug addiction or quackery, on the other.

I believe that if we can restrict the Pharmacopoeia to articles, the identity, purity and activity of which can be controlled and in a way guaranteed, there would be some promise of a more rapid development in our materia medica than has been evidenced during the past three or four decades; a period during which many of the other sciences relating to medicine have made unprecedented progress. You will, no doubt, agree with me that the Pharmacopoeia of the United States should be accurate in its statements, and that the information contained in its pages should be positive. If this were done, there would be no need for supplements to the Pharmacopoeia nor would there be need for revising the work more frequently than every ten years.

It might be deemed advisable to issue a supplement including new remedies, but even this would be really unnecessary in view of the annual publication of N. N. R., which is being widely accepted as a dependable source of information regarding new and nonofficial remedies. For other extra-pharmacopoeial articles the National Formulary and the proposed book on unofficial standards, now in course of preparation by the American Pharmaceutical Association, could readily be developed to provide the necessary descriptions and standards for every article that has been or will be used as medicine.

THE COMING ERA.

In practically all countries of the civilized world the National Pharmacopoeia is recognized as being a potent factor in the maintainance of the public health and in promoting a practical knowledge of medicaments and their limitations. Up to within a very recent period little or no attention has been devoted, in this country, to a scientific or systematic study of drugs and their uses. With the increase in number of pharmacologic laboratories, however, there has come an appreciation of the possibilities of work of this kind.

Among the more progressive colleges of medicine even now, pharmacology is receiving the attention that is rightfully due it, and there can be no doubting that the work of such men as Abel, Cushny, Hunt, Sollmann, Hatcher, Edmunds, Hale, Wood, Jr., Crawford, Salant, Houghton and others is destined to bring about a decided innova-
tion in American medicine that will, in time at least, entail a corresponding change in American pharmacy.

Whether we care to acknowledge the fact or not, there is no mistaking the indication that we are on the eve of a decided change in ideas, methods and requirements in our own field of work, and it behooves us to take heed of the warnings.

For two or three years we have heard numerous platitudes on the resources of the U. S. P. and the N. F., and the desirability of restricting medical prescribing to the articles enumerated in these books. Sollmann in his comments on the present-day U. S. P. and N. F. propaganda points out that while there are rather more good remedies and fewer bad ones in the Pharmacopoeia than there are out of it, the book itself is not a dispensation and can in no way take the place of brains either in prescribing or dispensing.

He also points out that physicians do not need more new drugs or more preparations of old drugs, but they do need to know more about a few drugs and how to use them with exact methods.

At a recent meeting of the City of Washington Branch of the American Pharmaceutical Association it was pointed out that the time to teach medical men how and why to use medicines is during the student period, and that this cannot be done effectively unless there is some generally recognized list of really valuable remedies.

It has been repeatedly pointed out that the U. S. P. enumerates drugs and preparations that are not only unnecessary but even objectionable, in that they lead to misleading statements in the exploitation of proprietary remedies or to the habitual use of fixed formulas by physicians in place of the guarded and scientific use of active medicaments.

With the work of the laboratory worker in pharmacology to point the way there is no longer any reasonable excuse for retaining inert or useless medicaments, providing we are willing to accept a reliable check on blind experience, so far as activity of medicinal substances is concerned.

In the future, let us hope in the very near future, the requirements for admission to the accepted list of best medicaments will be based on keen observation and positive knowledge, and that pharmacists, as such, will be among the first to recognize the validity of the requirement that the Pharmacopoeia be the accepted list of the best remedies that are available.

While there are at present many and varied opinions as to what the U. S. P. IX should be, I trust that we will be able, in the course of the sessions of this section, to discuss the question temperately and at length. I trust that our conclusions will be based on scientific reasoning, and that they will be acceptable to the Pharmacopoeial Convention and followed by the incoming Committee of Revision.

Let us ever remember that "The fruitful field of to-day is ours to work in, with the heritage of the past to guide us and the unknown possibilities of the future to lure us on to ever-increasing efforts to accomplish our daily tasks and to leave for generations yet unborn a field more fruitful and productive for the part that we have taken."

Action was called for on the Chairman's address, and on motion of Mr. Hallberg, seconded by Mr. Asher, it was ordered received, to take the usual course.

Mr. Wilbert resumed the chair and called for the reports of committees as the next business in order, and designated the Committee on Ebert Prize as the first to report. Mr. C. E. Caspari presented this report as follows:
Mr. Caspari explained that the decision of the committee was reached after considerable correspondence, and upon taking into consideration not only the paper which was presented by Mr. Gordin at the last annual meeting of the Association, but all those which had appeared for several years previously.

Mr. Hallberg suggested that Mr. Gordin's papers on this same subject had been presented to the American Chemical Society, and asked if he was liable to be awarded a prize by that Society also. He was also not entirely satisfied that this prize award had been made within the spirit of the prize-fund condition; he had so expressed himself at the Los Angeles meeting last year, and now, after having looked into the matter, he was convinced that his objection last year was correct, and he would like to ask the chairman of the committee if they had carefully reviewed the terms of the Ebert Fund as established.

Mr. Caspari replied that the committee had carefully considered the conditions of the award, and while the reward might not be in accordance with a very strict interpretation of the conditions laid down as applying to the prize, at the same time he did not think the committee had varied materially from its conditions. As to the publication of these papers in the Journal of the American Chemical Society, he was quite sure that all these papers, with the possible exception of one, had been read before this Association before publication by the American Chemical Society, and if that Society chose to award a prize after the papers had been read before this Association, it was "up to them."

Mr. Hallberg, said, that with this explanation, he would withdraw his objection.

The Chair thereupon declared the report of the committee approved as read.

The report of the Committee on Drug Market was called for, and Chairman Patch made the following report:

REPORT OF THE COMMITTEE ON DRUG MARKET.

Your committee have had a very brief interval since notice of their appointment, and cannot submit a very extended report.

Since the last meeting several observers have called attention to the wide range of results obtained in conducting alkaloidal assays. Dr. A. B. Lyons gives the results obtained by nine chemists assaying aconite root by market samples of extract of nux vomica presumably assayed by the various manufacturers, and labeled to contain 5 per cent, strychnine, to actually assay from 4.32 to 7.2 per cent., and nine samples of fluidextract of
belladonna leaf labeled to contain 0.3 per cent. alkaloid to assay from 0.25 per cent. to 0.39 per cent. This is not a very complimentary result after having had a number of years' experience with the methods used. Dr. Dohme has confirmed the statements of other observers, that there is no rapid deterioration in preparations of alkaloidal drugs, excepting in the case of coca, aconite and physostigma, while the change in these is not appreciable within six months.

It has been demonstrated that phosphorus is not a practical ingredient for tablets, as it rapidly oxidizes and is lost. On the other hand, dispensed in a proper pill mass it remains unchanged for a long interval of time.

Reports of convictions in different sections demonstrate that due care is not exercised in making simple pharmaceuticals. Preparations that are simple solutions, like tincture of iodine, spirit of camphor, liniment of camphor, spirit of anise, spirit of peppermint, etc., have been found of only 10-16 the official strength. In many cases it is absurd to think deliberate wrongdoing was practiced. Some of the most reputable and pain-taking druggists have been convicted, and the only possible explanation has been carelessness on the part of their assistants in making the products. In many cases it is hard to believe that the proprietor would deliberately sell a preparation below strength under any circumstances, and the sale of the article in question is so limited and the saving in cost so immaterial that there is a total absence of motive.

We notice convictions from the sale of mercurial ointment under strength. In one case the product was made by the leading manufacturing chemical house of the country and afterward assayed by a distributing house and pronounced to be 50 per cent. mercury, or U. S. P. It had stood in a warm place and softened, permitting the mercury to separate, and the druggist had not taken pains to triturate to uniform condition before dispensing. This plea could not be accepted by the health authorities, particularly as they had a sample that had not separated under similar conditions of temperature. Unfortunately they were misled, as the product used for comparison was not U. S. P., but had part of its lard replaced by wax to enable it to stand summer temperature better.

Acetic fluidextract of bloodroot is a source of annoyance on account of variability. Samples of drug assayed 4.06, 5.32, 4.48, 5.46, 5.6, 5.16, 5.04, 4.9, 5.6, 6.16 per cent.

Flext. U. S. P. ’90, with no special precautions, assays over 3 per cent, flext. 1900 acetic from some drugs will assay 3.5 per cent., but other lots of drug containing much resin will not yield the alkaloid to the aqueous acetic menstruum. A lot of drug assaying 5.6 per cent. percolated with large excess of acetic menstrum, and concentrated, gave a product loaded with extractive assaying only 1.96 per cent. The residual drug, dried and assayed, gave 4.06 per cent. alkaloid.

The necessity for the examination of products made by the best houses is seen in the fact that a lot of potassium bromide was distributed assaying only 47.05 per cent. of potassium bromide, while it contained in addition 47.04 per cent. sodium bromide and 5.91 per cent sodium chloride.

It is plainly evident that this mixture would not have been shipped intentionally, as its cost would be more than that of potassium bromide. On return of the product the shippers practically confirmed above assay.

H. H. Rushy expresses the conviction that there is not one-tenth the adulteration as was found five years ago. He instances the case of a large Eastern drug house recalling its stock in the hands of retailers and jobbers and substituting it by other stock. Examination of this recalled stock revealed its adulteration by the addition of foreign matter.

The presence of stems and other impurities in drugs has been largely ignored by the U. S. P. It is plain enough that when the woody tissue of a drug is inert the inclusion of a large percentage of woody stem is quite as active in degrading the activity as the addition of sand, sawdust or olive pits.
Nomenclature devices.—Since the government has prosecuted dealers for selling powdered colocynth containing the seeds, the practice has come into vogue of selling the same labeled “Colocynth apple.” It is hardly likely that any pharmacist would reject a shipment because it was so labeled. The dealers, however, declare that the name “Colocynth apple” is not in the Pharmacopoeia and that they may adulterate it as much as they choose. A similar case is the sale of male fern containing all its chaff and other refuse, the word “natural” being added after the title Aspidium.

The following table covers items reported upon to date.

Acid Citric.

Frequently contains free sulphuric acid equivalent to 1 per cent. or 1.5 per cent. of citric.

10 barrels assayed 99.05 per cent. to 100 per cent. No sulphuric acid. E. L. Patch.

Acid Hydriodic Dilute.

Often contains excess of potassium bitartrate; often 10 per cent. W. L. Scoville.

Acid Lactic.

Quite a difference is found between hot and cold trituration.

Aconitine.

Varies in physiological test from 1 in 450,000 to 1 in 650,000. W. L. Scoville.

Ammonia Water, Stronger.

Bought near the source of manufacture often runs above 28 per cent. Shipped any considerable distance, especially in warm weather, runs between 26 per cent. and 28 per cent. W. L. Scoville.

30 carboys assayed from 25.91 per cent. to 30.48 per cent. All had some empyreumatic odor on neutralizing. Only C. P. product readily answers U. S. P. test. E. L. Patch.

Asafetida.

Pharmacopoeial product is rarely obtainable, although better grade than formerly. The crude should be replaced by purified product and the powdered drug excluded from use. One sample contained 19.25 per cent. alcohol-soluble matter and 44.4 per cent. ash. Was heavily adulterated with chalk. E. H. Gane.

There has been constant improvement in quality until within the past two months when there has been a sudden renewal of heavy adulteration by the addition of sand or ground rock. Possibly this has been done to create the impression that a good asafetida cannot be obtained and influence the committee on revision in favor of lower standards. New and effective adulterants consisting of gummy matter closely resembling the drug in appearance, have resulted from the peculiar U. S. P. requirements regarding ash, which do not agree with those regarding solubility. The addition of these gummy matters is worse than that of inert matter and necessitates the visit of a competent investigator to the region of collection of this drug.

H. H. Rusby.

Asafetida.

Balsam Peru.

Is misbranded because it does not come from Peru. The sulphuric acid and lime tests are unreliable. A test should be had for the so-called synthetic balsam. The Dietrich test works well. E. H. Gane.

Belladonna Leaf.

The quality is greatly improved. The usual assay is around 3/4 per cent. The addition of scopola leaves still continues. The upper portion of the belladonna stem, not exceeding 3/4 inch in thickness, is quite as rich in alkaloid as the leaves. H. H. Rusby.

5 lots assayed 0.3 per cent., 0.38 per cent., 0.4 per cent., 0.31 per cent., 0.2 per cent. The last contained a considerable admixture of other leaves and belladonna. It is still difficult to obtain a leaf assaying 3/10 per cent. alkaloid. The amount of extractive in the leaf is often so great as to make it impossible to prepare solid extract of official strength. E. H. Gane.

All samples of the leaf assayed met 0.3 per cent. or better. Only one assayed 0.35 per cent. A. H. Clark.

Assayed from 0.26 per cent. to 0.27 per cent. E. L. Patch.

9 samples of fluidextrac of belladonna leaf labeled to assay 0.3 per cent. assayed from 0.25 per cent. to 0.39 per cent. C. Koch.

Belladonna Root.

The presence of poke root in this drug has practically ceased, and it has been gradually improved in character from every point of view. H. H. Rusby.

3 lots assayed 0.44 per cent., 0.49 per cent., 0.485 per cent. E. L. Patch.

Benzoin.

A definite limit of solubility in warm alcohol should be given. 20 per cent. insoluble in alcohol is not excessive in good samples of Sumatra benzoin. 2 samples of exceptionally fine quality gave 93.65 per cent. and 92.65 per cent. soluble in alcohol, with ash 1.05 and 0.70. E. H. Gane.

Different lots assay from 74.5 per cent. to 87.5 per cent. alcohol-soluble. W. L. Scoville.

Cacao Butter.

Varies in melting-point from 32.5° to 38° centigrade. Enough to make trouble in suppositories of varying composition. W. L. Scoville.

Calamine.

The original native product is no longer to be had. Mixtures of barium sulphate colored with iron oxide have taken the place of the genuine. Sometimes a little oxide of zinc or carbonate of zinc has been added, and sometimes the color has been an aniline color. As there is considerable call for this, would suggest the adoption of formula by the trade, that of the British Pharmaceutical Codex, for the fictitious product, being satisfactory. E. H. Gane.

Calcium Phosphate, precipitated.

None can be had strictly pharmacopoeial. The majority of houses state that they can supply technical only. The assay of this product is from 1.1 per cent. to 4 per cent. chloride. A lot labeled 2 per cent. chloride assayed 3.9 per cent. The best lot obtainable, guaranteed to be U. S. P., had 0.5 per cent. chloride. E. L. Patch.

Camphorated Oil.

Of 208 samples 107 were below the standard. The entire lot ranged from total absence of camphor to 27 per cent. Conn. Agri. Experiment Station.

8 samples assayed 3.4 per cent., 10.4 per cent., 19.6 per cent., 20 per cent., 20 per cent., 20 per cent., 21.4 per cent., 23.8 per cent. A. M. Alley.
Caraway Seed.

Has been offered practically free from oil. Pharmaceutical Era.

Saigon Cassia.

Catechu.

88 per cent. soluble in alcohol, 3 per cent. ash; 68 per cent. soluble in alcohol, 3 per cent. ash. E. L. Patch.

Cerium Oxalate.

The commercial article is of very varying composition. One must specify the pure to get the proper product. E. H. Gane.

Cerisein.

Varies in melting point from 58° to 65° centigrade. W. L. Scoville.

Lots of clove have been found mixed with clove stems and freed from oil. Pharmaceutical Era.

Cochineal.

2 samples 5 per cent. ash and 8.2 per cent. ash. E. H. Gane.

Cochineal Silver.

22.5 per cent. ash; Black, 6 per cent. ash. E. L. Patch.

Colchicum Seed.

0.52 per cent., 0.56 per cent., 0.52 per cent. E. L. Patch.

Colchicine.

4 lots melted at 116°, 119°, 122°, 126° centigrade. Evidently pure colchicine is not easily obtained in commercial quantities. W. L. Scoville.

Collodion.

One lot of flexible contained but 75 per cent. of the required amount of solids. E. L. Patch.

Cream of Tartar.

4 samples. 2 adulterated. Mass. State Board of Health.

Digitalis.

Much poor foxglove offered for import and the clashes between importers and inspectors have been numerous. Owing to the sensitive nature of the constituents of the drug, even a little carelessness in drying or preserving can result in great damage. The importers and large dealers are mostly quite innocent of all traces of knowledge concerning such matters, so they cannot understand why a drug should be rejected which is merely "off color" or "just a little blackish." H. H. Rusby.

Echinacea.

Substituted by spurious root, possibly parthenium. John Moser.

Elm Bark.

10 samples. One was adulterated with wheat starch, one with corn starch, eight were pure. P. P. Mitchell.

Goldenseal.

2 lots, 3.1 and 2.7 hydrastine. E. H. Gane.

Of 30 samples only one was below 2.5 per cent. Most were below 3 per cent., some 4 per cent., one 4.5 per cent. A. H. Clark.

Gumrac.

One sample, a fine clear gum, was 98.65 per cent. alcohol-soluble and contained only a trace of ash. E. H. Gane.

Guaranu.

4 lots: 4.4 per cent., 4.2 per cent., 4.5 per cent., 3.7 per cent. E. H. Gane.

Heroin.

The genuine varied in melting from 164° to 171° centigrade. W. L. Scoville.

Honey.

Adulterated with glucose, invert sugar, colored with coal-tar dye. Pharmaceutical Era.
Hyoscyamus.

There has been a great improvement. Now it is far more common to find it yielding 0.12 and 0.15 than below 0.08. H. H. Rusby.
5 lots assayed 0.051, 0.074, 0.044, 0.060. Two of the lots were annual leaf. E. H. Gane.
4 lots assayed 0.086, 0.0505, 0.0584, 0.0669. E. L. Patch.

Insect Powder.

Adulterated with ground stems and not ground from flowers only, as it should be. One sample from one of the largest pharmaceutical manufacturing houses was composed wholly of ground stems. Such products are sold below the cost of the genuine. E. H. Gane.

Iodine, Tincture of.

58 samples ranged in iodine content from 1.27 to 8.8 Gm. in 100 Cc. and in potassium iodide content from 1.06 to 8.9 Gm. in 100 Cc. L. D. Havenhill.

Of 49 samples 17 were below the standard. Conn. Agri. Exper. Station.

3 samples were 49 per cent., 56 per cent., 58 per cent. of the pharmacopoeial standard. Mass. State Board of Health.

Ipecac.

2 samples assayed below 1.75 per cent., 3 below 2 per cent. 6 above per 2 cent. A. H. Clark.
8 lots assayed 2.18, 2.33, 2.28, 2.4, 1.97, 2.26, 1.97, 2.4. E. L. Patch.
4 lots assayed 1.05, 2.1, 2.22, 2.19. E. H. Gane.

Reduced Iron.

11 samples assayed over 90 per cent., 7 contained sulphide, all were free from arsenic. L. O. Taytor.
All lots assayed from 90 per cent. to 97 per cent. W. L. Scoville.

Jalap.

12 lots assayed 9.78, 10.79, 8.17, 8.30, 10.30, 11.14, 7.72, 17.42, 7.19, 10.9, 7.91, while 8 bags of new crop assayed 23.88 per cent. resin with only 1.25 per cent. ether soluble. This wide variation shows the advisability of using the resin in place of the powdered drug in official preparations. E. H. Gane.

Lemon Extract.

82 samples examined. 29 adulterated or below standard. 25 illegally labeled. 1 sample contained wood alcohol. Conn. Agri. Exper. Station.

Licorice Powder, Ext.

1 lot consisted almost entirely of caramel, probably due to excessive heat in evaporating and drying. E. H. Gane.

Litharge.

Often contains small amounts of red lead. W. L. Scoville.

Lupulin.

1 lot contained 20.5 per cent. sand. E. H. Gane.

Mercurial Ointment.

3 samples were only 26.6 per cent., 9.12, 26.87 per cent. of official strength. Mass. State Board of Health.

Myrrh.

Much of the whole gum imported contains a varying proportion of gum acacia, probably due to careless collecting. E. H. Gane.

Of 7 lots the alcohol solubility ranged from 35 to 44.7 per cent. W. L. Scoville.

Mustard.

1 lot was colored with Martius yellow and adulterated with capsicum. Pharmacetical Era.
Nux Vomica.

Is adulterated with powdered olive pits, also with filings of the nut of phytelephas macrocarpa, the corajo or vegetable ivory. Pharmaceutical Record.

9 lots assayed 0.96, 1.16, 0.93, 1.25, 1.24, 1.28, 1.22, 1.23, 1.19 per cent. strychnine. E. L. Patch.

9 samples extract of nux vomica labeled U. S. P. standard 5 per cent. strychnine, assayed from 4.32 per cent. to 7.2 per cent. Christopher Koch.

Cottonseed Oil.

One barrel was mixed with Soya bean oil. Owing to the high price of cottonseed oil immense quantities of Soya bean oil have been imported and in many cases used for the former. E. H. Gane.

Oil of Eucalyptus.

5 out of 7 lots had 75 per cent. to 79.5 per cent. cineol. One lot only 50 per cent. W. L. Scoville.

Oil of Lemon.

Under present regulations it is impossible to admit oils adulterated with washed or exhausted oil of lemon or C. P. citral. Geo. Leuders.

The washed oil is a very poor product. Seems to be lemon oil from which the citral has been largely extracted. It has sp. gr. 0.843, rotation, + 60° 25'. E. H. Gane.

Oil of Lavender.

2 samples test as follows: Sp. gr., 0.896; rotation, — 4° 35'; refraction index, 1.464; linalyl acetate, 40.56 per cent.

Sp. gr., 0.891; rotation, — 5° 45'; refraction index, 1.4648; linalyl acetate, 29.54 per cent. E. H. Gane.

Olive Oil.

16 samples contained cottonseed oil. One contained 90 per cent., one was 100 per cent. cottonseed oil. Mass. State Board of Health.

Green olive oil is frequently a very inferior quality, at times containing over 40 per cent. of free fatty acid calculated as oleic.

Some dealers have reported this grade of olive oil adulterated with red oil, but a high acid number alone is not proof of this admixture. E. H. Gane.

Sample of Malaga olive oil contained cottonseed oil. Other samples stood all U. S. P. tests. Saponification value, 191.2; iodine number, 84.41. E. L. Patch.

Oil of Pennyroyal.

2 samples, sp. gr., 0.919; rotation, + 90°; sp. gr., 0.922; rotation, + 8° 50'. Both had poor odor. E. H. Gane.

Oil of Rose Geranium.

There is a very wide variation in the oil of commerce. 4 samples from large importing houses gave the following results: Sp. gr., 0.906; rotation, —7° 5'; acid no., 9.19; geranyl tiglinate, 26.2 per cent.; residue on evaporation, 7.75 per cent.

No. 2. Sp. gr., 0.892; rotation, 7°; acid no., 5.57; geranyl tiglinate, 20.2 per cent.; residue on evaporation, 3.5 per cent.

No. 3. Sp. gr., 0.901; rotation, —7° 5'; acid no., 6.96; geranyl tiglinate, 19.4 per cent.; residue on evaporation, 6.35 per cent.

No. 4. Sp. gr., 0.905; rotation, —8°; acid no., 22.3; geranyl tiglinate, 22.6 per cent.; residue on evaporation, 8.05 per cent. E. H. Gane.

Gildemeister & Hoffman give for French oil—sp. gr., 0.897 to 0.905; rotation, —7° 30' to —9°; geranyl tiglinate, 25 per cent. to 28 per cent.

African or Algerian oil—sp. gr., 0.892 to 0.90; rotation, —6° 30 to 10°; geranyl tiglinate, 19 per cent. to 29 per cent.

Spanish oil—sp. gr., 0.897; rotation, —10° to 11°; geranyl tiglinate, 35 per cent. to 42 per cent.
Oil of Tar.
A product meeting the U. S. P. requirements is not obtainable. A more accurate definition of just what is intended by the official description of oil of tar is required. All sorts of products are sold as oil of tar, as the following figures show:
Sample 1. Color reddish-brown. Odor good. Sp. gr., 0.996; 40 per cent. distils between 315° and 444° Fahr.
Sample 2. Color almost black. Odor tarry. Sp. gr., 1.044; 40 per cent. distils up to 450° Fahr.
Sample 6. Color light brown. Odor good. Sp. gr., 0.963; 70 per cent. distils below 370° F. Sold as crude tarry spirit.
Sample 7. Color light brownish-red. Sp. gr., 0.861; 60 per cent. distils below 350° F. Sold as light tarry oil.
Sample 8. Color reddish-brown. Odor good. Sp. gr., 0.958; 75 per cent. distils below 400° F.

Papain.
Sample 1. 1 part digests 12.25 parts of dry fresh beef fibrin in neutral solution. 17 parts in alkaline solution.
Sample 2. 15.35 parts in neutral solution, 17.8 parts in alkaline.
Sample 3. 14.7 parts in neutral solution, 19.1 parts in alkaline.
Sample 4. 15.5 parts in neutral solution, 19 parts in alkaline. E. L. Patch.

Pepsin.
Usually of good quality and digestive power. One lot examined tested less than 1 to 1000.

Podophyllin.

Ash 1 per cent. E. H. Gane.

Resorcin.
Varies in melting-point from 110.5° C. to 114° C. W. L. Scoville.

Saccharin.
Tests 425 to 550 times as sweet as sugar. W. L. Scoville.

Salophen.
Adulterated with 25 per cent. acetonilide. Zernik.

Sanguinarine Nitrate.
Only 52 per cent. pure. Contains potassium nitrate, sugar of milk and aniline dye. L. H. Bernegau.

Resin of Scammony.
6 samples adulterated with starch. W. M. Quinlan.

Scammony.
A fictitious gum is in French commerce. Brownish cakes, less dense than the genuine, more porous fracture, less active. Pharmaceutical Journal.
Caustic Soda.
Runs quite uniform. 85 per cent. to 96.4 per cent.  W. L. Scoville.

Sodium Carbonate.
Means several things in commerce. On U. S. P. basis from 34.4 per cent. to 97.2 per cent. of official. Water of crystallization is, of course, the chief feature in the lower percentages.  W. L. Scoville.

Sodium Phosphate, Dried.
None of the dried sodium phosphate on the market is U. S. P. It contains 9 per cent. to 25 per cent of moisture.  H. A. Bradshaw.

Spermaceti.
The commercial does not comply strictly with official requirements, being usually lower both in sp. gr. and melting-point. This is not due to adulteration, but because all of the sperm oil has not been removed. For this reason the U. S. P. test for stearic acid often gives fallacious results. Sp. gr., 0.897; melting-point, 42° C.; saponification number, 142; iodine number, 7.57. Insoluble in 90 per cent. alcohol.  E. H. Gane.

Solution of Chlorinated Potassa.
Some samples were free from chlorine. Others assayed 0.608, 0.62, 1.64, 2.06, 2.08, 1.5, 2.77, 2.86 per cent.  J. G. Molineaux.

Solution of Chlorinated Soda.
Assayed 0.13, 0.359, 0.33, 0.615, 1.63, 1.66, 2.79, 2.83, 3.01, 3.05 per cent.  J. G. Molineaux.

Spirit of Anise.
1.5, 4.4, 5.2, 2.5, 3.5; 3.8, 5.8, 5.9, 6.3. 6.3. 4.8 per cent. of oil anise, instead of 10 per cent. by volume called for.  Mass. State Board of Health.

Spirit of Ether, Comp.
Of 25 samples only 1 had the required amount of ethereal oil. Some had none. R. A. Grimes.

Spirit of Nitrous Ether.
15 samples assayed from 1.97 per cent. to 3.71 per cent. None contained the 4 per cent. required. Only 2 were above 3.5 per cent.  J. B. Sawtelle.

Spirit of Peppermint.
7.1, 6.8, 6, 6.11, 6.95 per cent., instead of 10 per cent. by volume required.  Mass. State Board of Health.

Stramonium.
Not one sample was up to the original 0.35 per cent. All met 0.25 per cent. A. H. Clark.
Has been found considerably adulterated with chopped chestnut leaves, and large shipments have been rejected for this reason. If stramonium leaves are pure and good they will assay 0.35 per cent., and 0.3 per cent. should be insisted on.  H. H. Rusby.
6 samples assayed 0.41, 0.37, 0.29, 0.34, 0.31, 0.35 per cent.  E. L. Patch.

Strophanthus.
A paper will be presented at the Scientific Section to show that strophanthus hispidus is a stronger and better drug than strophanthus kcombe. This claim seems to be inconsistent with the standard on which it is based, and shows to the great need of more attention from physiologists and therapeutists as to what our standard should be. Our Revision Committee has signally failed in defining the properties on which standards should be based. It has done much work on chemical properties, much of which is valueless because the materials employed are not fully authenticated.  H. H. Rusby.
Suppositories of Lead Acetate, 3 grains each.
10 lots of 12 each were assayed, and were found varying in acetate of lead contents from 0.058 grain to 6.77 grains. L. F. McBride.

Tragacanth.

Vanilla Extract.
Of 81 samples 30 were below standard. 18 were illegally labeled. Conn. Agri. Exper. Station.

For the Committee, Edgar L. Patch,
L. F. Kebler,
Wilbur L. Scoville,
H. H. Rusby.

May 2, 1910.

Mr. Kebler presented in abstract a supplemental report to that of the Committee on Drug Market, embodying the results of investigations by the Government along the line of adulteration and misbranding of drugs.*

Mr. Hallberg asked Mr. Kebler whether he had found drugs and chemicals professing to be U. S. P. adulterated, or below standard; and if so, whether there was a statement to that effect on the label.

Mr. Kebler replied that this was true in a few instances. He said the importers frequently labeled a product as being deficient, but in that case there was a proviso in the law which made it possible to exclude it, if it was deleterious to the public health. As a rule, he said, there was no declaration on the label. Strenuous efforts were being constantly made to import products and then label them at the port of entry to comply with the Pharmacopoeia; and then, after these products got into the country, nobody knew what became of them.

Mr. Rusby also spoke of the constant attempts being made by the dealers and importers engaged in interstate commerce to change the labels slightly, so that the name of the drug would be one not found in the Pharmacopoeia, and then claim they were not liable. He gave examples of such attempts in ground male-fern and colocynth. Mr. Rusby said it was the same old story, and if anybody thought that adulteration of imported drugs was a dead letter, he was very much mistaken. He said this practice was not confined to one locality, and the only way to put an effectual stop to it was for the States to join hands with the Federal Government and make a determined effort to stop it. It was useless, for instance, for the Department of Agriculture to establish standards that were ignored in the States. Unless such articles were found in the Pharmacopoeia or in some other book recognized by the State authorities, he did not see how these practices could be stopped. He thought that no one method would suffice, but that all the methods that could be thought of would have to be used.

* This report has unfortunately disappeared; all efforts to locate it have proven unsuccessful and a duplicate could not be obtained.—The General Secretary.
Mr. Wetterstroem, of Cincinnati, wanted to know about the Dispensatories as a standard, but Mr. Kebler explained that only the U. S. Pharmacopoeia and National Formulary were recognized as standards under the Federal Law.

Mr. C. Caspari, Jr., asked what standard would be assumed for an article not official in the Pharmacopoeia at all, and found to be adulterated with mineral matter. Mr. Rusby replied that his instructions were to examine products that came in powdered form, to see whether they were truthfully named, and fit in quality for use in making medicinal preparations; and that in a case of that kind he would recommend to his superior that such articles be rejected, because not of fit quality for medicinal use. Then the importer would make a protest.

Mr. Caspari said, Take the case of kamala, a drug not recognized in the U. S. Pharmacopoeia, but recognized in the German Pharmacopoeia, the latter giving the standard of ash as not exceeding five per cent., while the product came into the country with 10 or 15, or even 25 per cent. of ash; in other words, grossly adulterated. He wanted to know if the party in this case would be liable to prosecution. Mr. Rusby responded that if it was interstate commerce goods, he would declare it was not truthfully named. He suggested that Mr. Kebler could probably throw some light on this proposition.

Mr. Kebler stated that in a great many cases the Government did take the common standard for its guide. Where an article was not official in the present Pharmacopoeia, but was in the Pharmacopoeia of 1890, the latter would be taken as the standard. While the question had never been tested, he thought that where there was a description well recognized by the trade, the court would sustain such a standard. He took the case of chestnut leaves as an illustration. On the other side of the proposition he took Hoffman’s Anodyne as an illustration, a name applied indiscriminately to at least three different products: in Germany one would get one thing, while in this country, under the Pharmacopoeial name, he would get quite another. Then if he bought it under the name of the commercial article, he would get a mixture of ether, alcohol and water in equal parts. He could hardly see how a fixed standard could be provided in a case of this sort.

Mr. LaWall said that in Philadelphia, where the importers and wholesalers worked in harmony with those who examined drugs, when an adulteration was reported, they simply refused to accept it. If the importers insisted on admission, it might become a question as to how to enforce the standard. Up to the present, they had no difficulty at all. He used an importation of adulterated quince seed, which they had re-shipped without trouble, as an example.

Mr. Kebler thought Mr. LaWall had brought up an entirely different subject from that presented by Mr. Caspari, and said if the quince seed
was to be used in interstate commerce his position would be perfectly correct. It was a fact that a cabinet officer had absolute jurisdiction under the Federal Law as to whether or not a product should come into this country, and if the Secretary of Agriculture said that a product was a violation of the law, there was no appeal from his decision.

The Chair stated if there was no further discussion the report would be accepted, and the Section would pass on to the next business, which was a paper by Henry Kraemer, upon the subject of "A New and General Adulterant of Roots and Drugs." The reading of this paper, however, was passed for the time being, on account of the absence of the writer.

The Chair stated that the next paper was one by Albert Schneider, of San Francisco, upon "The Necessity for Drug Reform." He said the paper was a long one and the author was not present. He called for action thereon.

Mr. Hallberg moved to receive and refer by title, and the motion prevailed.

Mr. LaWall presented the following paper upon "Ash Standards for Vegetable Drugs."

ASH STANDARDS IN DRUGS—ARE THEY NECESSARY?

BY CHARLES H. LAWALL AND HENRY A. BRADSHAW.

In 1897* one of the authors of this paper (LaWall) published an article giving data upon a number of commercial specimens of drugs as regards ash, moisture, and in some cases active principles. Attention was called to the fact at that time that the ash of drugs is a fairly constant factor, which, while probably of little direct bearing upon the physiological activity, nevertheless indicates, especially in root drugs, freedom from excessive amounts of inert earthy material due to careless methods of collecting and drying, and the fairly constant ratio which is found in a given drug may be taken as a criterion in part of its freedom from other materials which might be mixed with it and in which the ash ratio differs appreciably. When it is seen that chestnut leaves contain only in the neighborhood of 4 per cent. of ash, while the solanaceous leaves, such as belladonna, hyoscyamus and stramonium, contain from 13 per cent. to 30 per cent., the value of the ash factor as confirmatory evidence of admixture is realized.

No attempt was made in the present work to estimate moisture and calculate results to the dry basis, as was done in the paper referred to, as it was found at that time that the difference never amounted to more than 10 per cent. of the weight of the ash and was more than counterbalanced by the slight variations in different samples of the same drug. The following list, therefore, represents the commercial drug in the air-dried form,

* A. J. P., Vol. 69, p. 137.
and mainly comprises routine samples of drugs which have been imported in the whole state and of which a representative sample of authentic drug was taken for the determination. The arrangement has been made alphabetical, italicizing those titles of drugs which are official. In some instances it will be noted that a number of samples of one drug have been examined, while in many others but one or two figures are given. This is due to the relative frequency or infrequency with which the drugs are imported at Philadelphia, and the results are submitted to be taken in conjunction with the previously published work upon this subject. This work, together with any results which may be presented later, will serve as a guide to those who are entrusted with the task of fixing standards for the next U. S. Pharmacopoeia, as the authors believe that an average ash standard appended to each drug described would be of advantage and value in fixing its identity.

Viburnum Prunifolium, 7.30.
White Agaric, 1.5.
Wild Cherry Bark, 3.4.
Mr. A. R. L. Dohme, asked the author if there was anything like uniformity in the samples, and Mr. LaWall replied that there was a great deal of uniformity; that the range was very slight in any one given drug, by the figures as shown in actual practice, while other drugs showed a very different proportion of ash.

Mr. Rusby suggested another valuable use for ash determination. He said it was sometimes difficult to tell what quantity of stem a drug contained; it might be known there was too much woody tissue in the ground drug, but it was difficult to tell how much, and in such cases the ash determination would sometimes enable one to do that.

Mr. Stanislaus said he had found on examination of vegetable drugs that very often there was mineral matter adhering to them to a considerable extent. He knew of instances where upwards of eight per cent. had been found in the ash. Mr. LaWall responded, that, as stated in the paper, these were simply commercial drugs as they entered the market, and were such specimens as would pass current without criticism as to their appearance.

Mr. Rusby said that henbane was apt to lie on the ground in sandy soil, and the dirt would get into the leaves, and it was very difficult to wash it out sometimes without breaking them. He related some of his experiences in dealing with importations of this drug.

Mr. Kebler said he considered ash determination in their work in the Government laboratories as of great value. He said they were now experimenting in other directions, also. He instanced the case of colocynth, where, by the ash determination, the chemist could say whether or not seeds are present. If a considerable quantity of seed was found, the ash was proportionately low. From the experience they have had, he thought it very desirable to include in the Pharmacopoeia a maximum ash limit. He favors to meet such conditions as Mr. Stanislaus referred to, where a considerable amount of earthly material often adheres to the plant. The leaves of digitalis, henbane and the like are usually contaminated with a considerable amount of inorganic matter, but he thought that some maximum limit should be fixed.

Mr. C. E. Caspary said that the determination of the alkalinity of ash had been very important in the detection of spurious extract of vanilla; that it was the practice in certain localities to make an extract of vanilla by dissolving vanillin in alcohol, and then using a certain amount of alkali to dissolve certain resinous matter from exhausted beans, calling that ex-
tract of vanilla; about the only way it could be detected would be to determine the alkalinity of the ash.

The Chair stated that the paper would go to the Publication Committee, without objection, and it was so ordered.

The Chair stated that the next thing for consideration was two papers on nomenclature, the first by Oscar Oldberg, which was in print, and of which the author had sent an extended abstract, with the request that it be read. He said that, without objection, the abstract would be read, instead of the paper. Mr. Richtmann, Associate on the Committee, then read the abstract referred to, the full text of the paper being as follows:

THE SO-CALLED "LATIN TITLES" FOUND IN THE PHARMACOPEIAS.
BY OSCAR OLDBERG.

The Pharmacopæia of the United States, Ninth Edition (Eighth Revision) p. lxii, calls the technical names of its drugs, chemicals and preparations the "Latin Titles." It is an almost universal custom to call them "Latin names," even in text-books and reference works of pharmacy and materia medica which fail to explain that very few of these technical titles are really unaltered Latin words, that less than one-third of them contain a syllable derived from any Latin word, and that while a Latin appearance has been imparted to most of them by arbitrarily giving them terminations such as Latin words commonly have, many other pharmacopœial titles do not even have Latin endings.

Technical terminology is absolutely necessary to every branch of science. The mastery of materia medica, chemistry and pharmacy would be impossible without the concurrent mastery of their special technical terms. Such terms must each have a fixed and unambiguous significance, and the enormous number required of these could never be supplied without coining entirely new words whose meaning is then specifically defined. These new terms are fashioned out of materials furnished by words from many different languages, from the names of men and places, and from other sources. Many technical names are formed out of parts of two or more words from one or more languages, dead or living. A few are old names which have ceased to have their original meaning.

The really Latin words employed unaltered in pharmacopœial nomenclature are less than one hundred, and most of these are adjectives. Latin names of individual substances contained in the pharmacopæias are so extremely rare because botany, chemistry and pharmacy were unknown to the people who made the Latin language.

LESS THAN FIVE PER CENT. OF THE WHOLE NUMBER OF NOUNS USED AS PHARMACOPEIAL TECHNICAL TITLES ARE TRUE LATIN NAMES.

Immediately upon the publication of the seventh edition ("Sixth Revision") of the Pharmacopæia of the United States I grouped the 457 words employed in making up its 997 titles according to their derivation.
Of these 457 words 372 are nouns and 85 adjectives. I counted carbo, carbonem, carbonas, bicarbonas and subcarbonas as five of the 457 words and as of Latin origin; and the words chlorum, chorlas, chloridum, and chloratus were counted as four words of Greek origin.

Of the 372 nouns used as titles of distinct substances I found 147 described as of Greek and 108 as of Latin derivation, leaving 117 derived from all other sources, so that considerably less than one-third, including the unaltered Latin names, are of Latin origin, and most of these 108 titles contain but one or two syllables taken from Latin words.

Of the entire 457 words (nouns and adjectives) out of which the 997 titles of that pharmacopoeia are composed:

171 are described as of Greek origin.
153 are said to be of Latin origin.
21 are reported as of mixed Latin and Greek derivation.
20 are derived from Arabic words.
45 are derived from words of other languages.
29 from names of countries and places.
18 from names of persons.

But all of these titles are called "Latin names," and the statement is often made that in order to understand them well it is necessary to know Latin. Another statement frequently made is that the Latin names of the drugs, chemical compounds and pharmaceutical preparations are used because "Latin being the language of science" those names are understood in all countries. These statements are singularly out of harmony with the purpose of technical terminology which is the highest degree of accuracy.

Latin scholars understand the true Latin words, such as aqua, ferrum, lac, mel, and the few other really Latin titles to be found in pharmaceutical nomenclature, and they will as unerringly know that the terms jaborandi, kamala, looch, catechu, gambir, kermes, cusso, buchu, carrageen, quebracho, and a considerable number of other titles given in now living pharmacopoeias, can not be Latin.

Latin scholars would fail to recognize the "Latin names" potassium (from the English words pot and ashes), belladonna (composed of the Spanish words bella, beautiful, and donna, lady), manganum (said to be, together with the title magnesium, derived from the name of the town of Magnesia in Asia Minor), and grindelia (named after Mr. Grindel).

As for the technical titles containing one or more syllables taken from Latin words, it must be admitted that the most intimate knowledge of Latin would throw little if any light upon their significance, as may be seen from the names cimicifuga (from cimex, bug, and fugare, to drive away), cornus (from cornu, horn), frangula (from frangere, to break), illicium (from illicere, to allure), pulsatilla (from pulsatilis throbbing), serpentina (from serpent, snake), ustilago (from urere to burn), valeriana (from the name Valerius, or its origin valere, to be strong.)
A Latin scholar knows the general meaning of the word “extractum,” but he would know little or nothing of the pharmaceutical meaning of the title extractum, or of trituration, spiritus, suppositorium or emulsum.

Evidently the statement that the official technical titles of drugs, chemicals and preparations are their “Latin names” is 95 per cent. untrue. A semblance to Latin has been arbitrarily imparted to most of these titles by giving their nominatives Latin-looking endings and forming their genitives according to the five Latin declensions. This universal custom has given rise to the false notion that they are Latin names, whereas they are at most latinized, or rendered latinic in appearance, whenever found practicable and deemed necessary or desirable. This artificial latinization of the pharmacopoeial nomenclature has been in use for generations and has been found of great practical utility in most instances.

But laymen who do not understand the necessity of scientific technical terminology have often accused the medical profession of writing prescriptions in Latin for the purpose of keeping patients in ignorance of the kind of medicine prescribed. These would-be reformers do not and can not know that technical terms, whether Latin or not, are unavoidably unintelligible to all persons except the trained specialists who use them, and that it is in reality the technical terminology and not Latin that they object to. What they demand is prescriptions which they can understand, not knowing that such a thing if possible would be dangerous. They complain that “Latin prescriptions” are written in order to conceal the character of the medicines, not knowing that ample and precise information concerning their ingredients under the names by which they are prescribed and dispensed, is freely accessible to all men in the Pharmacopoeia and other technical works, but that this like all other scientific information can be given only in language which laymen can not understand. They ignorantly propose to destroy or impair an efficient means of protection to the public which has been painstakingly built up and improved through generations by the physicians and pharmacists, the specialists who alone are able to perform that duty, and whose sole object was and is the prevention of errors and abuses. When a layman into whose temporary possession a prescription may fall can read it, or thinks he can do so, he sometimes abuses it by advising friends and neighbors, who, in his opinion, have the same trouble as the patient for whom the prescription was written, to use the same medicine. Deplorable results have not infrequently followed.

Crudities still exist in the technical nomenclature of most pharmacopoeias, but corrections are being made to bring the style of the titles into harmony with scientific progress and with recognized linguistic rules and sense of fitness, as well as to make them more accurate and convenient to those who are to use them.

In all that we do toward perfecting our technical pharmaceutical titles
we ought to bear in mind that ultimate international uniformity is highly desirable, and that it is by no means unattainable. Conflict with scientific truth ought not to be permitted, but very recent pharmacopoeias still continue to call some oxides acids, and to use the old title "hyposulphis" while translating it thiosulphate.

Such a crude title as "æther petrolei" should no longer be employed for a hydrocarbon, and Hg₂Cl should not be called "hydrargyrum chloratum" while HgCl is called "bichloratum," these latter titles having reference to the old and discarded molecular formulas.

Errors of this sort were corrected in the Pharmacopoeia of the United States when last revised.

Changes are easily made, because the technical terms we use are to a very great extent coined words of our own making. We should thankfully accept suggestions from botanists, chemists and philologists as far as we can do so without sacrificing practical advantages of greater value to us than strict conformity to the opinions of other specialists who are not sufficiently familiar with the peculiar requirements of pharmacy.

That minor modifications are easily made is shown by the fact that within the brief space of forty years we have had such a variety of names, form and spelling in different pharmacopoeias as seen in the following examples; the element arsenic has been called arsenum, arsenium and arsenicum; antimony has been called stibium, antimonium, and antimonum; we have had the names kalium and potassium, natrium and sodium, aluminiwm and aluminum, manganum and manganum,iodinium and iodum; chloral and chloralum, amyl and amylium, gelatina and gelatinum, cresol and kresolum, chloroformum and chloroformium, menthol and mentholum, iodol and iodolum, etc.

A pharmaceutical nomenclature constructed without due regard for the requirements of the writers of prescriptions can not be the best. They want titles as brief and as easily written as possible, and when long titles seem unavoidable they should be made to be as easily abbreviated as may be possible without loss of clearness and without violating grammar and good form. Such titles as hexamethylenamina, methylthioninæ hydrochloridum, and sulphonethylmethanum are abominations.

Shall we continue this absurd style of titles until we reach such names, already official in recent pharmacopoeias, as: "diethylmalonylcarbamidum," "acetylpaminophenolium salicylicum," "trimethylbenzoxyypiperidinium hydrochloricum," and "diethylsulphonmethylaethylmethanum"? The Latin in these names consists of the terminal um.

I am unable to find sufficient or consistent reasons for the titles "hydrochloride" and "hydrobromide" applied to the salts formed by the alka-

loids with hydrochloric and hydrobromic acids. The fact that the hydro-
gen atom of the acid enters into the compound formed need not be indicated by the official title of the compound, and we do not, and cannot
name the alkaloidal salts formed with other acids in that manner; we do not say hydroxulphate, hydrophosphate or hydroxalicylate of quinine, etc. Instead of burdening writers of prescriptions with such a long title as "coca inae hydrochloridum" it seems to me that coca inae chloridum is much to be preferred; it is shorter, it cannot be misunderstood and it corresponds with the titles of the salts formed by ammonia with the acids.

It is unnecessary here to mention all cases of needlessly long titles, but there are several more. One of the long adjectives used is "exsiccati", which should be shortened to sicci, or even to siccus. Every useless letter should be eliminated, but we have actually lengthened several brief titles without gaining anything thereby. Nothing was gained by changing chloral to chloralam, or amyl nitris to amylis nitris, and the genitives æthyl, methyl, amyl, phenyl, glyceryl, alcohol, guaicol, menthol, phenol, and thymol are more convenient than æthylis, mentholis, alcoholis, etc. Chemists continue to coin such names as fast as needed. Shall we cease them and tack on caudal appendages which are wholly superfluous? Not one of them is Latin either before or after. The rule we formerly followed in the American Pharmacopoeia under which technical titles ending in -al, -ol, or -yl were treated as indeclinable words was one of practical value and should be restored. Every title which can without impropriety be treated as indeclinable should be so treated. This title had the unqualified approval of no less an authority than Charles Rice. It was a mistake to give coca the genitive cocaæ without reason.

Among the useful changes of official "Latin names" made in the last Revision was the shortening of valeriane to valerate. Among the changes which should not have been made is the substitution of the philosophically awkward title fluidextractum, which can not with propriety be sufficiently abbreviated as can the title extractum fluidum which prescription writers can abbreviate to extr. fl. The suggested abbreviation "fl. extr." is not an abbreviation of fluidextractum, but of fluidum extractum.

The endings -ina for the latinic names of alkaloids and -imum for "neutral principles" should stand, together with the terminations -ine and -in for the English names, because they have a recognized practical value to both chemists and pharmacists.

It would not be surprising should physicians decide that the titles of pharmaceutical preparations of plant drugs would be more convenient if inverted so that when arranged in alphabetical order all the different preparations of the same drug fall together in a group. The grouping of all tinctures in one place, extracts in another, and so on, is of minor value to the pharmacist and of no value to the physician, but the grouping of all opium preparations under opium, aconite preparations in the same place where aconitum is, etc., would be useful to both professions. It would be seen, at a glance, what preparations of opium the Pharmacopoeia contains from which the physician may choose; and methods of
preparation, menstrua, doses, and other points of difference could be at once compared. Digitalis, digitalis extractum, digitalis extractum fluidum, digitalis infinita and digitalis sinctorum should be found together, and if digitoxinum is introduced in the Pharmacopoeia it should be placed with the other forms of the therapeutic agent digitalis.

The inorganic chemical compounds have technical latinic titles constructed according to three entirely different methods—the Berzelian, the German and the English. Silver oxide is called "argentum oxydatum" in countries where the German method is employed, it is called "argentii oxi-datum" in the United States and Great Britain, and if it were included in the Swedish Pharmacopoeia it would there be called "oxidum argenti-cum." Silver nitrate is called "argentii nitras" in the United States, "argentum nitricum" in Germany, and "nitas argenticus" in the Scandinavian countries, France and Russia.

It has recently been suggested in our country that in order to make due distinction between ferrous and ferric and between mercurous and mercuric compounds, some such titles as "ferro sulphas" and "ferri sulphas," "hydragyro chloridum," etc., might be used. It is to be hoped that such extraordinary construction will never be adopted.

Whenever changes are made in pharmacopoeial nomenclature we must bear in mind that ultimate international uniformity ought to be promoted. Modern chemical nomenclature in English, German and all other living languages is to a great extent already similar. We say ferrous and ferric chloride, mercurous and mercuric iodide, argentic nitrate, arsenous oxide, etc. The Berzelian system of latinic titles for inorganic chemical compounds is in harmony with this modern chemical nomenclature, and should be preferred to the other systems. It is natural and easily applied.

It is extremely unfortunate that we have the two names kalium and potassium for K, the two names natrium and sodium for Na, and stibium and antimonum for Sb. The names potassium, sodium and antimonum will never replace the names kalium, natrium and stibium, but the names corresponding to the chemical symbols will prevail. In striving to bring about ultimate world-wide uniformity we must not lose sight of the rule of the survival of the fittest."

We have already made a beginning in the recognition of modern chemical nomenclature in the English technical titles of the American Pharmacopoeia by adopting the terms ferrous and ferric, mercurous and mercuric arsenous (iodide), etc. We might with great advantage extend this general method to the latinic titles in all cases where specially applicable. Ferrous sulphate should be called ferrosus sulphas, ferric chloride would be called ferricum chloridum, mercurous chloride would have the latinic title hydrargyrosum chloridum mite, arsenous oxide should be called arsenosum oxidum, arsenous iodide would become arsenosum iodidum, and we should construct similar latinic titles in all analogous cases.
These titles are as natural and permissible as those of acidum sulphuricum and acidum sulphurosum.

Northwestern University.

The Chair then called for a paper by Mr. Hallberg, on "Nomenclature of the U. S. Pharmacopœia," and Mr. Hallberg presented his subject as follows:

THE NOMENCLATURE OF THE U. S. PHARMACOPOEIA.

BY C. S. N. HALLBERG.

The origin and evolution of the nomenclature of an art or science is necessarily similar to that of a general language, since it is language applied to some special subject or art.

A nomenclature should have these attributes in order of their importance: 1. Descriptiveness. 2. Definiteness. 3. Flexibility. 4. Brevity. 5. Euphony.

The whole tendency of nomenclatures has been in this direction, as it must continue, best to serve their purpose.

Imagine what we have escaped from in the following respective examples:

Cranium humanum decapitatum,
Vel signe ignei preparatum.
Liquor Fuliginis splendentis alkalicus.

From complexity to simplicity is the slogan, and singularly enough in this respect the older the country the more radical; the younger the more conservative.

In Latin countries the languages have undergone the greatest changes. Spain and Italy write "Farmacopea." The present German written in Austria is scarcely recognized as the "original" German and is more advanced than that of the more modern German Empire. The English language is the most conservative of all, although it has undergone great changes since Shakespeare's time.

The Continental countries have an advantage inherent to their political status as distinguished from English-speaking countries, in that the governments, through their royal academies, etc., revise the languages at regular periods and the changes are accepted "nolens volens."

Contrast this simple process of "fiat" with the ludicrous attempt recently in this country at correcting the etymological monstrosities of some of the simplest English words, synthetized from a mixture compositum of Roman, Norman, Teuton, Scandinavian, Celt and Welsh, the conglomeration called English.

Even the strenuous former executive met his Waterloo—swift and sure—when he tampered with the sacred linguistic prerogatives of the Government Printing Office.
He may successfully traverse the Dark Continent and with trophies of untold victories attached to his belt of the ferocious beasts of the Jungle. He may be received as the conquering hero by the crowned heads of Europe.

He may enjoy the plaudits of the universe as the apotheosis of the virility of the twentieth century, but lest he lay his vandal hands on the dear old English language—Beware!

THE FIRST PHARMACOPOEIA.

The present U.S. Pharmacopoeial nomenclature is practically that of the first Pharmacopoeia of the U.S. of 1820; the only changes being in the chemical and botanical parts. The pharmaceutical portion is scarcely changed at all, except for additions of some new classes of preparations, such as fluidextracts.

The Pharmacopoeia of William Brown, M.D., of Lititz, Pa., 1778, contained 100 articles, divided into two classes:

1) Medicamenta interna, with 84.
2) Medicamenta externa seu chirurgica, with 16.

It contained twenty-five classes of preparations, fourteen of which are still official, so that only twenty new classes of preparations have been added, since this first attempt at a collection of the administrative forms of medicines.

The Pharmacopoeia of Surgeon General Tilton of the Continental Armies, 1777, was somewhat similar.

The Pharmacopoeia of the Massachusetts Medical Society 1808, endeavored to follow the Edinburgh Pharmacopoeia, but in the translation from the Latin some changes were effected.

UNITED STATES PHARMACOPEIA 1820.

The U.S. P. of 1820 in the Preface states: "In the formation of the American Pharmacopoeia, the General Convention and their publishing committee have had to encounter those difficulties which must always attend the first publication of works of this kind." "The Selection of a Materia Medica; the formation or adoption of preparations, and compounds, and the establishment of a pharmaceutical nomenclature, have constituted their chief labor." "On each of these departments of the work they have endeavored to bestow that degree of careful inquiry and mature deliberation which the importance of the occasion demanded; and have pursued the course, which appeared to them best suited to supply the wants, and promote the interests of the medical community in all sections of the country."

Relative to the scope of articles contained it states: "The system of retrenchment might no doubt have been more vigorously exercised without ultimate disadvantage to the interests of medicine." "But it was thought
to be at present more conducive to the public good, to retain on the list all those medicines which were believed to be so much in use in any part of the United States, that their omission would occasion inconvenience to physicians and apothecaries, and render the book less applicable to their wants."

On the Nomenclature it expresses itself as follows: "It has been endeavored that the nomenclature adopted in this work should be conformable to the present language of science, divested of as much of its prolixity as can be done consistently with clearness and distinctness. It is conceded that the essential properties of names ought to be expressiveness, brevity, and dissimilarity. Where these qualities can be preserved without too great a departure from language previously in use, they afford the best grounds of a convenient and intelligible nomenclature."

The binominal botanical nomenclature of the London and Edinburgh Pharmacopoeias was substituted by the single title, usually the generic name of the plant, instead of the systematic name and usually with the name of the particular plant-part used added.

The chemical nomenclature of the London Pharmacopoeia in which the base precedes in the compounds, was adopted and is retained to this day, as it is in the British and the German and several others, while in the French and Scandinavian Pharmacopoeias the acid radical precedes in names for compound.

This is probably due to the use of French titles instead of Latin and in the Scandinavian to their adaptation of the Berzelian nomenclature.

**BOTANIC AND CHEMICAL NOMENCLATURES.**

It is believed that the present botanic and chemical nomenclatures cannot be improved on. Possibly the designation of synonyms for a few articles would for certain practical reasons be desirable. For example: Thebaicum for opium; also for cocaine, morphine, quinine, etc. It is believed that this would be appreciated by physicians who may then resume writing prescriptions for such articles instead of dispensing them.

The nomenclature of the synthetics is a serious problem and should receive much thought and study. It is again suggested that a systematic scheme be devised to form titles for these complex compounds on the plan followed in the last revision, which is believed to be the best solution of this perplexing question.

**THE PHARMACEUTICAL NOMENCLATURE.**

The nomenclature of the pharmaceutical preparations is of the most importance and, in view of the constant attempts to its corruption and of its being ignored by even those manufacturers who otherwise try to conform to adopted nomenclature, its adherence should be insisted on.

The medical profession should be vigorously and persistently impressed
with the incontrovertible fact that only in the most scrupulous adherence to the pharmaceutical nomenclature lies safety. It is short, catchy, euphones, sometimes therapeutically suggestive, often meaningless, coined trade-names, which are the glittering bait held out to the young and unsophisticated practitioner. If he bites, he is lost. Laymen are voracious and will also bite and usually swallow bait, hook and line, leaving nothing for the practitioner but the sad reflection that he was a member of the finny tribe for whom Illinois stands sponsor among the surnames of States.

The nomenclature is the crux of the proprietary medicine question: strict adherence to it will put the wholesale compounders out of business and restore the pharmacist's practice in preparing and compounding.

The following classes were comprised in the U. S. P. 1820, with the number of preparations of each:

<table>

This comprises 21 classes with 253 preparations. The U. S. P. of 1900 comprises 33 classes with 450 preparations. It will thus be seen that the U. S. P. in 90 years has increased about one-half in the number of classes and not quite doubled in the number of preparations. Roughly considered, the demands of the thirteen original colonies with the "Western Reserve," comprising a population of the State of New York, required one-half as many kinds of pharmaceutical preparations in their Pharmacopoeia as does the vast continent with nearly ten times the population gathered from all points of the earth, not counting any provision for Cuba, Porto Rico, Hawaii, or far-distant Guam or the Philippines. Does the little coterie in the territory of the thirteen original colonies recognize that to fully realize its functions the Pharmacopoeia of the United States should more nearly be based on the Pharmacopoeia Universalis?

The Chair called attention to the striking list of a few pharmaceutical names gathered together here, compiled from eighteen different pharmacopoeias, as illustrating the need of some uniformity along this line, and the difficulties of the situation. He said this would be especially noticed in regard to the names of chemical substances. The English Pharmacopoeias were quite distinct from the others. Those of the Continental
countries were fairly uniform, and there were many reasons why the pharmacists of America should consider the adoption of the Continental titles. He said there had already been adopted in this country titles for pharmaceutical preparations which were much more uniform than the names of the newer chemical remedies, which offered a very serious stumbling-block.

Mr. Raubenheimer continued the discussion of the subject of nomenclature, in which he said he had always been interested. He pointed out some of the troubles attaching to the nomenclature of chemical products in foreign Pharmacopœias. He agreed with Mr. Hallberg in the view that the nomenclature of the U. S. P. was far superior to that of any of the other Pharmacopœias. The German and Russian titles were an illustration of how confusing to the pharmacists of this country these things could be, and how easily a mistake would be made in putting up a prescription. He gave some illustrations to show this.

Mr. Good said he had never been very much in love with the word "fluidextractum." The idea was, of course, to adhere to the alphabetical arrangement of titles, but there would be no very great violation of that principle by making a group of extracts, and a group of fluids, and in that way the old titles could be given to groups of preparations.

Mr. Lyons did not concur with Mr. Good in this view. He could see no objection to the name "fluidextractum." However, he believed that the Pharmacopœias of the world must come together. He thought the Latin names for chemical compounds could not be discarded by one nation and retained by another. What was needed was to have these things come before a body in which all the nations were represented for careful discussion, and then what was decided there should be accepted by the different nations, just as the Pharmacopœias of the world in the main have accepted a certain strength for tinctures and potent drugs.

Mr. Kebler said he had given the subject of pharmaceutical nomenclature considerable attention, and had found from experience that it was quite satisfactory. One reason why he made this statement, aside from personal observation was, that no one, to his knowledge had ever used the Pharmacopœia as an example of bad nomenclature, and one could rest assured that with the hundreds and thousands of products that were misbranded, if the parties guilty of this practice could have found the bad examples to supplement their views—to in that way have substantiated their views—they would have done so. Mr. Kebler said he could see no objection to the use of the word "fluidextractum." He thought it a little cumbersome at first, but he had come to rather like the word. It was a word that could be readily condensed, and no mistake could be made.

The General Secretary lightened the seriousness of discussion by raising a little stir over the pronunciation of the word "nomenclature." He said he felt sure that Mr. Hallberg would like to know the proper pronunciation of this word, as well as anybody who used it, and that the proper
pronunciation was "nomenclature," and not "nomenclature." He said that this matter had been settled five years ago in this Section.

Mr. Stevens, Mr. Payne, Mr. Good, Mr. Hallberg and the Chairman all took a hand in the discussion of the correct pronunciation of this word, with the usual result of a difference of opinion.

Going back to the use of the word "fluidextracum," Mr. Payne argued for the use of the word, and said it could be readily abbreviated to "Fl. Ext."

Mr. Stevens admitted that this word "fluidextractum" had a strange sound to him at first, but he had gotten used to it, and it could be readily abbreviated into "Flext."

Mr. Hallberg said the word was used in this country everywhere, and he believed it was the German Pharmacopoeia's word. From the start it had been abbreviated into "Flext." He favored the word from the standpoint of safety, and spoke of its value to workers and students.

Mr. Hallberg, referring to his paper, said he thought he had not brought in anything about the elision of the final e in the bromides and chlorides, but expressed the hope that this question would not be overlooked, as something ought to be done in the matter. He thought it was a matter that should be decided before the Pharmacopoeial Convention. A committee had been appointed from this Section to have a conference with the Section on Pharmacology of the A. M. A., and the Section of the American Chemical Society, in regard to this subject.

The Chair asked if it was desired to decide this question at this time, but Mr. Hallberg suggested that it go over until tomorrow afternoon, and it was so ordered.

The Chair called for the nomination of the officers of the Section for the coming year as the final order of business for the afternoon.

Mr. Stevens said that, following the established custom, he wanted to name for the office of Chairman Mr. A. H. Clark, of Chicago, and for Secretary Mr. William O. Richtmann, of Satsuma Heights, Florida. This motion was seconded by Mr. Stanislaus and Mr. Puckner.

On motion of Mr. Stanislaus, the Section then adjourned.

SECOND SESSION—WEDNESDAY AFTERNOON, MAY 4, 1910.

The second session of the Session on Scientific Papers was called to order by Chairman Wilbert at 3:30 p. m., and the Chair stated that the first order of business was a discussion of the report of the Committee on U. S. Pharmacopoeia, "the most important business, perhaps, before this entire meeting."

Chairman Beringer, of the Committee on U. S. P., said that the report was rather voluminous, consisting of some fifty-eight pages, and in addition
there were reports from a large number of sub-committees, and likewise a number of personal investigations which were not complete, which would probably be reported on next year. He suggested that, in order to get the report before the Association in the proper way, it would be best to read it by sections and discuss it. This was agreed to.

The Chair urged the greatest brevity possible on the part of the members in their remarks on the report, as only in that way could the Section cover any considerable amount of ground, and said that to facilitate matters, any section not objected to would be considered as adopted.

Mr. Beringer then proceeded to read the report of the committee as follows:

REPORT OF THE COMMITTEE ON THE UNITED STATES PHARMACOPEIA.

The report of this year must be considered as a supplement to and a continuation of the voluminous report submitted last year. It is exceedingly difficult to harmonize the views of the members of a committee by correspondence, and no attempt was made to do so, but each member has been encouraged to independently submit his views and results of work accomplished; other subjects were reported on by sub-committees. As the report must be prepared in advance of the annual meeting and without an opportunity for conference, it is deemed advisable to continue the same style as adopted in the report of last year. As the views expressed are largely the personal opinions of individual members that may not be shared by the others, the name of the author is given after each comment.

During the year, there has been some correspondence between the Chairman of the Committee on U. S. P. of the American Medical Association and the Chairman of this committee, endeavoring to establish some plan of co-ordinating the work of the two committees. The desire for co-operation is mutual and while no definite scheme has yet been evolved, the effort should be continued and a plan formulated that will permit of the extension of the fraternal relations between these two committees and the establishment of systematic co-operative work on selected subjects and along fixed lines for each committee.

Like the preceding report, it is composed very largely of criticisms, yet it is hoped that at least a fair proportion of these may be of assistance to the committee on revision. It is recommended that copies of these reports be filed with the Convention for the use of the Committee on Revision.

ADMISSIONS AND DISMISSEALS.

This is always a bone of great contention, yet it is one of the problems that must be decided early, and decided on some definite plan, before the revision can make much progress. In the pre-conventional discussions a wide divergence of opinion has been evidenced. Among some of the medical writers, the attempt to reduce the official list to their personal views and individual preference is apparent. Equally erroneous is the proposition that the Pharmacopoeia should comprise only drugs and remedies tested pharmacologically and that admissions should be decided on the basis of established therapeutic activity. This beating of scientific tom-toms has sounded well and has attracted the unwary and may even lead a few pharmacists astray. The pharmacopoeia never has been and never can be made an authority on therapeutics and no pharmacopoeia has ever been compiled on such a basis. Who is to decide the medicinal action and value of each drug? The pharmacologists' and the chemists' decisions are disputed
by the practical clinician and no two doctors will agree upon the relative merits of the drugs contained in any comprehensive list. This is demonstrated by medical history and practice throughout all the ages and the profession has always been divided into schools and camps each with their views as to the proper remedies that should be used.

The pharmacopoeia is and must remain a book of standards for medicines used sufficiently to warrant standardizing and uniformity in formulas. It cannot be a book for one class of physicians or section of the country, but must be broad and comprehensive enough to serve the reasonable needs of all physicians in all parts of this country.

The tendency in the recently published foreign pharmacopoeias is toward an extended list of official articles, and this is well illustrated in the recent revision of the French Codex, and the same needs exist here and must be recognized. There is special danger to the pharmacists in a too restricted list, as it leaves them without standards and authoritative formulas for many of the articles dispensed. Use and use alone should decide the admission of any article and entire disuse the dismissal.

It is interesting to note some of the suggestions that have been made for admission and deletion and the effect such changes would have on the character of the book and the practice of pharmacy. For example, consider some of the recommendations from the American Medical Association. The Section on the Practice of Medicine recommends the dismissal of lard. The adoption of this would necessitate endless changes in the appearance and formulas for ointments and cerates. Also the deletion of such well known vegetable astringents as geranium, rhus glabra, rubus and krameria, with all of their preparations even yet quite frequently prescribed. Also oil of coriander and cassia fistula, ingredients in confection of senna and syrup of senna. Also fluidextract of sabal which has never been official. The declaration for the dismissal of compound powder of acetanilide is accompanied with the statement that “There does not seem any reason for retaining this combination.” But as the members of this same Association annually prescribe and dispense several tons of this powder, should there not be a fixed standard?

The Section on Ophthalmology recommend that mitigated lunar caustic, olate of atropine, and extract of stramonium should be dropped. Of course there had never been any field of use for these in their special practice, but how about their fellow practitioners who prescribe stramonium extract in ointments and suppositories. These examples simply serve to illustrate that the view-point of the recommender must be considered. It is not the opinion of the medical author or expert that must in this matter be alone accepted, but the needs of the entire army of doctors in active practice throughout the entire country must decide. No small committee of experts can decide for the medical profession what it shall prescribe and what it shall not prescribe, and any such attempt at limiting the armamentarium of physicians will fail.

The Committee are of the opinion that the use of the following items makes them worthy of consideration for admission to the official list, provided that they are not controlled by patent or trade-mark rights:

Acid, Acetyl Salicylic, Adrenalin Hydrochloride, Ammonium Hypophosphite, Ammonium Sulph-Ichthyolate, Antipyrine Salicylate, Berberine Hydrochloride, Bismuth Betanaphthol, Bryonia, Calcium Glycerophosphate, Calcium Lactate, Catechu, Chlorobutanol (Chloretone), Chlorobutanol (Chloretone Inhalant), Cinchonidine Salicylate, Cotarnine Hydrochloride (Stypticin), Cotarnin phthalate, Creosote Carbonate, Crocus, Diethyl Barbituric Acid (Veronal), Dimethyl Antipyrine (Pyramidon), Fluidextract of Cottonroot Bark, Fluidextract of Sabal, Fluidextract of Zea, Fluorescein,
Glycocholates,
Colalin,
Chologestin,
Holocaine Hydrochloride,
11matropine Sulphate,
Hydrastine Hydrochloride,
Iron Valerate,
Liquor Alumini Acetatis, N. F.,
Maranta,
Mass Copaiba,
Morphine Diacetyl,
Morphine Diacetyl Hydrochloride,
Morphine Ethyl Hydrochloride,
Naphthol Benzoate,
Novocaïne,
Oleoresina Apii (Green Apiol),
Papaw, enzyme preparation,
Phenolphthailein,
Potassium Glycerophosphate,
Potassium Guaiacol Sulphonate,
Quinine Ethyl Carbonate,
Euquinine,
Quinine Valerate,

Saccharin (Soluble), the Sodium Salt of
Benzosulphimide,
Salophen,
Silver, proteid salt,
Sodium Cacodylate,
Sodium Cinnamate,
Sodium Glycerophosphate,
Sodium Perborate,
Sodium Peroxide,
Sodium Succinate,
Strontium Lactate,
Strychnine Arsenate,
Succinic Dioxide (Alphozone),
Suprarenaline Alkaloid,
Theobromine,
Theobromine-Sodium Salicylate,
Thiocol,
Thiosinamine,
Tincture of Bryonia,
Tincture of Pulsatilla,
Zinc Carbonate Impure,
(Calamine).

The following articles now official appear from the data in the possession of the Committee to be no longer used sufficiently to require recognition, and unless other information of use is reported, we are of the opinion that their dismissal should follow:

Acetum Opii,
Alumin. Hydroxidum,
Ext. Scopola,
Fld. Ext. Eupatorium,
Fld. Ext. Matico,
Fld. Ext. Mezereum,
Fld. Ext. Staphisagria,
Gambir,

Hedeoma,
Iodol,
Matico,
Mezereum,
Pimenta,
Preparations,
Troches of Gambir.

Report of Sub-Committee on Review of Foreign Pharmacopoeias.

It seemed desirable to limit the report this year to two points, viz., the relation of the U. S. and other pharmacopoeias to the Brussels treaty and the extent to which foreign pharmacopoeias have included substances proposed for admission to the U. S. P. by the committees of the A. Ph. A. and A. M. A.

(1) The Brussels Treaty. The Brussels protocol was prepared in 1902 and the treaty signed in 1906. Mr. Wilbert, in a paper recently prepared, has given the results of an examination and comparison of thirteen pharmacopoeias issued since the Brussels Conference. It is largely from this paper that the following facts are taken. There has been a remarkable degree of conformance with the International Standards. Thus as to the requirement of per cent. of drug strength in the case of the most important drugs: of a total of 260 titles, 131 did not comply before the Conference; now all but 15 do comply. Of these 15 cases of non-compliance, five, or one third, occur in the U. S. P.

As regards the total number of compliances, however, the U. S. P. stands far behind that of any other nation. In this connection Mr. Wilbert states:

"It has been pointed out by Greenish and others that of the first national pharmac-
poeias to be published after the signing of the protocol at Brussels, in 1902, the Spanish Pharmacopoeia leads by conforming to 96 per cent. of the requirements; the Belgian Pharmacopoeia conforms to 87 per cent.; the Dutch Pharmacopoeia, 81 per cent.; the Austrian Pharmacopoeia, 77 per cent., and the Pharmacopoeia of the United States to but 27 per cent. of these requirements. To arrive at these results, Belgium was compelled to modify 80 per cent. of the formulas, Spain 75 per cent., Holland 30 per cent., and Austria but 6 per cent. of the corresponding formulæ contained in the previous editions. Henry G. Greenish (Pharm. Journ., June, 1907, p. 832), in further discussing the same question makes the following comment: "The conspicuous failure on the part of the United States to bring its formulas into harmony with those of the agreement, as shown by the tables, and also the notes on the various preparations. is the more remarkable when considered in conjunction with the statement in the preface (of the U. S. P.) that "the recommendations of this (the International) Conference have been adopted by the Committee of Revision except in one or two instances." The more evident variations are in the nomenclature of the official substances, the strength of menstruum and the general non-compliance with articles 2 and 3 of the protocol."

Mr. Wilbert states further:

"In a paper on the then newly-proposed international standard tinctures of potent remedies (Am. J. Pharm., 1903, v. 75, pp. 20–27) I ventured the opinion that: The advantage that must be admitted in favor of the proposed international standard menstruum is that it would be uniform in strength for all extractive tinctures of potent drugs; that the keeping qualities of the preparations would be improved; that a smaller proportion of the inert materials would be extracted, and that, therefore, less precipitation would take place.

"The opinions expressed at that time have been amply verified in practice. With the single exception of tincture of ipecac, international standard tinctures, made more than seven years ago, are still clear and evidently satisfactory, while corresponding preparations, made with the U. S. P. VII menstruum of diluted alcohol, generally precipitated heavily within a few years at most.

"One perhaps important feature in this connection is that approximately 70 per cent. alcohol has long been recognized as being a much more efficient antiseptic than either more dilute or more concentrated mixtures of alcohol with water. This one property of 70 per cent. alcohol alone should warrant its careful consideration, on the part of the next U. S. P. Committee of Revision, for adoption as a routine menstruum in place of the diluted alcohol now generally prescribed."

The degree of non-compliance with the International Standards of the U. S. P. as compared with that of the pharmacopoeias with which the Spanish translation of the U. S. P. comes most into competition (viz., the French and Mexican) is especially striking. In speaking of the adoption of the normal drop-counter recommended by the Brussels Conference the Mexican Pharmacopoeia states:

"In pharmaceutical practice measures of capacity should not be used, but all medicaments, in general, should be weighed. When it is necessary to measure by drops any small quantity of liquid, use should be made of the Normal drop-counter prescribed by the Brussels Conference."

The introduction to the Venezuela Pharmacopoeia states as one reason why the U. S. P. is not suited to use in Venezuela is that it does not provide for the use of the metric system as followed in that and other countries using the metric system.

(2) Admissions. The accompanying table shows the extent to which a number of the drugs proposed for admission to the U. S. P. by the Committees of the A. Ph. A. and of the A. M. A. are contained in foreign pharmacopoeias.

(3) In connection with the frequently made argument that a number of the less widely used drugs should be retained in the U. S. P. in order to have legal standards for
them and the suggested remedy of stating that the standards for drugs dismissed from the 8th Revision shall continue to be valid, it is interesting to note that at least two foreign pharmacopoeias (the French and the Servian) already follow this plan.

</table>

As the associate member of the Sub-Committee on Review of the Foreign Pharmacopoeias, I am compelled to dissent from some of the views expressed above by my colleague concerning the Brussels International Conference of 1902 and the compliance or non-compliance of the U. S. Pharmacopoeia with its recommendations. Some of the criticisms directed at the U. S. F. in this connection are hardly fair as the critics should know that at the time this treaty was signed the 8th Revision was most likely going through the press and the time would not permit of a more thorough consideration of many of the debatable questions or radical changes proposed in these recommendations.

One of the delegates of the United States points out in his recorded account of this Congress that all of the previous international conferences had failed to accomplish the purpose intended and had been unproductive of any very definite or substantial results. The chief and most important distinction of this conference of 1902 "was its restriction to the consideration of plans for securing international uniformity in strength of potent remedies only. As a result of this limitation of its scope it is believed to have satisfactorily accomplished its task and to have achieved a measure of success which was not possible with undue range of discussion—which had characterized and rendered ineffective all preceding pharmaceutical congresses."

In so far as the discussion and the conclusions were limited to this scope for which

1 Proposed for admission to Ph. G. V by Imperial Board of Health.
2 Not recommended by Committee on Vaccines, etc., of the A. M. A., on ground that there is no satisfactory standard. (Reid Hunt.)
the delegates were assembled and empowered to consider, they have been generally approved and to a very large extent adopted in the United States Pharmacopoeias VIII and in the foreign pharmacopoeias published in recent years. But in the course of the proceedings, Dr. Power records that "Some special propositions were presented for consideration by a few of the delegates and these comprised a considerable number of detailed suggestions that had been previously elaborated and printed." "The delegate from Denmark likewise submitted special propositions for the unification of formulas for tinctures and medicinal wines, and for the adoption of the normal drop-counter of the French Codex of 1854." It is thus very plain that the congress busied itself with a great many subjects on which the delegates were not authorized to consult and commit their respective countries. It has been largely these "extra" subjects that have caused the greatest amount of criticism. It is recalled also that no harmonious conclusion could be reached about many of the subjects contained in the preliminary lists and these of course are not included in the articles of the protocol. It is particularly unfortunate that digitalin and aconitine were two of these for which international standards are especially desirable. While there are many excellent points in the articles covering the agreements it is exceedingly doubtful if some of these would not be changed if another conference was to be held at this time.

From an American way of thinking and working, the European continental method of weighing liquids and solids and the finished product is very unpopular and is not likely to be again attempted in this country. The failure of the effort in the U. S. P., 1883, demonstrated that this "will not go" in this country. Yet it was one of the leading features in the Brussels protocol.

Personally, I am far from being convinced that the U. S. P. has committed any error in not adopting 70 per cent. alcohol as the universal menstruum for the tinctures of potent drugs. It does not appear to be likely that this is the best menstruum for the extraction of drugs of such varying physical characters and chemical constituents. The critic admits that the tincture of ipecac was not satisfactory, and I fail to see how 70 per cent. alcohol can extract cantharides when it is difficult to exhaust the drug in making the tincture with alcohol.

Considerable criticism has been directed toward the pharmacopoeia because of its failure to adopt the so-called "international nomenclature." It does not appear that the congress was clothed with authority to dictate pharmacopoeial titles and the names used in the protocol were simply "proposed" and not mandatory, and were in each case accompanied by one or more alternatives and in tincture of nux vomica, wine of antimony and fluidextract of ergot the choice is offered in each of four different names. This does not indicate that universality of pharmacopoeial names was expected.

International nomenclature is one of the idealistic dreams like that of a universal language and universal peace and other Utopian ideas that from a purely ethical standpoint look very inviting, but are not practical in the present state of the nations. It must be admitted that a large number of the pharmaceutical names are for substances not known in ancient or medieval times and for which we have consequently no classical Latin names, and so new names have to be coined according to the fancy of the author of the name and the customs of the time and nation. The same method is shown in many of the Latin names for plants and animals. Consequently we cannot find any universal rule governing pharmacopoeial titles, each being guided largely by the customs and idioms of its own national language. It has become quite common to Latinize either botanical or the vernacular name of the drug or else a name under which it is prescribed by physicians. Very often the predominating idea is to prevent error and safeguard the patient, and after all is this not the most important consideration? Take, for example, the three names "proposed" by the Brussels Congress for Fowler's solution of arsenic—Arsenicals Liquor Fowleri, or Liquor arsenicalis Fowleri, or Kalii arsenicosi liquor. Could our
American physicians be induced to use either of these, or would the Pharmacopœia be justified in making a change in the present well-established title, creating misunderstanding and the liability to error?

Accepting Dr. Power's record of Article III of the protocol as a correct translation, the language used impresses me as if the delegates realized that this was one of the "extra" or "special" propositions not considered in the call and their authority did not extend to a binding conclusion. It is certainly far from a binding or even a positive declaration in favor and reads: "It would be expedient to adopt a normal drop counter, of which the external diameter of the dropping tube should be exactly 3 millimeters. In other words at a temperature of 150° C., and with distilled water, 20 drops should be equivalent to 1 grammes." Here again the difficulty comes in from the variance of American medical practice from the continental. If the normal drop counter could be based on the minim which is still the dosage drop that a majority of physicians have in mind it might meet with their favor (G. M. Berenger).

GENERAL PRINCIPLES TO BE OBSERVED IN THE NINTH REVISION OF THE U. S. PHARMACOPEIA.

On the eve of the convention for the ninth decennial revision of the Pharmacopœia, it is very appropriate and likewise very important that the members of this Association who are so vitally interested in the results of that convention and the establishment of standards that are absolutely correct, should give expression to their opinions and desires concerning the general principles that are to be observed in the work of revision. This is all the more important at this time as other interests have proposed certain untenable theories the adoption of which would be detrimental to the welfare and progress of true pharmacy.

Consequently, the committee have formulated a number of propositions each presenting some special subject as a principle to be observed in the revision and these are submitted for discussion with the hope that they will assist in crystallizing sentiment and serve as the basis for a satisfactory expression of your opinion and requests to the pharmacopœial convention.

1. Scope.—The Pharmacopœia shall be a book of standards for such substances as are sufficiently used as remedial agents to warrant recognition and the fixing of proper standards. We recommend that the limitations to the scope of the Pharmacopœia adopted for the 8th Revision and set forth in article 1 (See Introduction U. S. P. VIII—XXX) be re-adopted for the next revision.

2. Function.—The Pharmacopœia is not to be considered as an authority on therapeutics and the admission or deletion of any article is not to be considered as an indication of its medicinal value.

3. Doses.—That doses be continued in the Pharmacopœia under the rule adopted for the 8th Revision and that these be corrected wherever necessary, and that in addition, for potent remedies the maximum single and the maximum daily doses also be given.

4. Nomenclature.—That the present rule relating to changes in titles (Introduction fol. XXXI) be re-adopted with only such modifications as are necessary to comply with the subsequent suggestions.

5. Botanical Names.—That changes in the present botanical names be made only for well-defined reasons and such changes shall conform to the rules of the International Botanical Congresses.

6. Names for Synthetic Chemicals.—That for synthetic chemicals with lengthy chemical names, the committee coin wherever practical short euphonious titles contracted from the true chemical names and that the latter be always given as one of the English titles.

7. Purity Rubric.—That the purity rubric as introduced in the eighth revision be continued and extended wherever practical and especially as related to crude drugs.
8. Improved Descriptions and Definitions.—That the official definitions and descriptions be carefully revised so as to meet the present need as legal standards.

9. Committee on Drug Markets.—That the Committee on Revision be requested to appoint a special committee to make a thorough investigation of the quality of crude drugs in commerce both in this country and abroad, and to cooperate with the U. S. Government Departments in such investigations and that this committee be instructed to endeavor to determine the proper limits to variability due to soil and climatic condition or improper handling, and to suggest such improvements as can be introduced in collecting and marketing such wares.

10. Standards for Crude Drugs.—That reasonable and proper standards be introduced for crude drugs wherever practicable that will insure a satisfactory quality for the pharmacist and exclude substandard, fictitious or adulterated materials.

11. Standards for Powdered Drugs.—That the titles and standards be introduced for such drugs as are properly used in the ground or pulverized condition and where the standards for the whole are not applicable to the powdered drug.

12. Assay Processes.—That the assay processes be extended to all drugs and preparations permitting of satisfactory testing in this way, and that identity tests for the purity of the isolated active principle be included wherever possible.

13. Pharmacognostic Descriptions.—That with the description of a crude drug, brief pharmacognostic descriptions both macroscopic and microscopic where possible be given, and the appearance of the structural elements in the powder when examined microscopically as a means of detecting adulteration.

14. Methods of Storing and Preventing Deterioration.—That instructions be incorporated for the proper storing of each article and methods of preventing deterioration.

15. Time Limit on Drugs.—That a time limit of permissible use be fixed on each drug and preparation that is prone to deterioration or change of active constituents.

16. Fineness of Powders.—That the designation of the fineness of powders be continued to be stated in terms of the number of meshes to a linear inch of a sieve through which the powder will pass, and that the diameter of the wire in the official sieves be fixed.

17. Powdering Drugs.—The powdered drug to represent the entire drug. Where the drug can be powdered without residue this should be required; in other cases, the allowable tailing or residue should be determined.

18. Synonyms.—That the proper English name under which the article is commonly sold be given along with the Latin title of each drug and preparation, and that a list of less important or less frequently used names be published with the other tables as a table of synonyms.

19. General Processes.—That type processes and general formulas be introduced wherever possible so as to prevent useless repetition in the text of formulas.

20. Descriptions of Galenicals.—That terse and concise descriptions of the official preparations be given after each formula.

21. Sterilization.—That a chapter on sterilization be introduced describing the proper methods for sterilizing medications and apparatus, and indicating to what preparations each method is especially applicable.

22. Atomic Weights.—That the current International Standard of Atomic Weights be adopted for all official chemical formulas and calculations based thereon.

23. Structural Formulas.—That structural formulas be not given in the revision of the U. S. P.

24. Discriminating Tests for the Druggist.—That the simplest identification tests for the needs of the pharmacists be stated first in the list of tests and be in special type.

25. Official Methods for Physical Constants and Chemical Determinations.—That there be included official methods for determining the usual analytical data such as
specific gravity, melting and congealing points, ash, solubility, extractive, percentage of water, alcohol, ether, etc.

26. Normal Temperature.—That an agreement be made between the Committee on Revision and the United States Bureau of Standards by which a uniform official national normal or standard temperature shall be established for determining such constants as specific gravity and solubility, and at which apparatus should be certified.

27. Definition of Admitted Impurity.—That the character and composition of the innocuous impurities allowable in medicinal chemicals be stated with proper limitations and tests.

28. Distinction between Medicinal and Technical Substances.—That the statement relating to substances sold solely for medicinal purposes in the preface of the 8th Revision page XXXIX be re-incorporated in the 9th Revision, and that the principle involved be stated clearly and more forcefully if possible.

29. Weights and Measures.—That the metric system of weights and measures only be used in the descriptions and formulas.

30. Alcohol Content.—That with each formula for a preparation containing alcohol, the average alcoholic content of the product be given.

ASSAY PROCESSES FOR ORGANIC DRUGS.

REPORT OF CHAIRMAN OF SUB-COMMITTEE ON ALKALOIDAL ASSAY PROCESSES.

It has not been possible for the sub-committee to carry out any systematic study of the assay processes of the Pharmacopoeia. These processes have been freely discussed in current pharmaceutical literature, and the new committee will have the benefit of a multitude of criticisms and suggestions, the value of which can be determined only by patient experimental work. Some of the newer Pharmacopoeias, notably the Swiss, have adopted innovations in the general plan of alkaloidal assays as well as in many details of the processes, all of which must be studied with unbiased mind by the new committee. Only a few specific recommendations, therefore, will be offered here.

1. The paragraph on alkaloidal assay by immiscible solvents, p. 578 of the present Pharmacopoeia, should be rewritten and should include a general assay process in full detail (a) for crude drugs and (b) for fluidextracts. The general process may well be modeled after that adopted by the Association of Official Agricultural Chemists. In the text of the Pharmacopoeia, specific assay processes should be given only where the general assay process is inapplicable, or requires material modifications. Otherwise reference should be made to the model process in the Appendix. It will be the task of the new committee to make the model processes as universally applicable as possible.

2. In assay processes for different preparations of the same drug, details as far as possible should be carried out in precisely the same manner, and the directions should be given in the same words.

3. Aconite Assay. The new committee should ascertain whether there is any real reason why aconite should not be assayed by the same general method as belladonna, etc., and should also test the question whether alkaliometrical titration of the alkaloid obtained in the assay of this drug is not liable to lead to grossly erroneous conclusions. It is certain that titration results often indicate more “aconitine” than the actual weight of the crude alkaloid. The gravimetric method of the new French codex should be investigated and may possibly prove to be satisfactory.

4. Cinchona Assays. In assays of cinchona bark, a preliminary treatment of the powder with hydrochloric acid on a steam bath seems to be a capital improvement, insuring complete extraction of the drug, and materially shortening the time of the assay.

In determining the “ether soluble” alkaloid, in the present pharmacopoeial assay, the ethereal solution is kept at a temperature of 15°C. ten minutes to allow the less soluble
alkaloids to crystallize out. The time is insufficient, unless the separator containing the solution is shaken continuously during the ten minutes—and in summer it is not easy to maintain the required low temperature while the shaking is in progress. The time should be extended to 30 minutes, a vigorous shaking of the separator for at least a minute in the outset being prescribed.

The quantity of "ether soluble" alkaloid determined by this very simple procedure seems quite as satisfactory a criterion of the therapeutic value of the drug as any determination that can be easily made of the single alkaloid, quinine.

5. Conium Assays.—It is simpler and better to determine conine by alkametrical titration than by weighing as in the pharmacopoeial assays.

6. Colchicum Assays.—The colchicine obtained in the present assay processes is never quite pure, and in the attempt to remove impurities one is liable to lose alkaloid. A method of determining the alkaloid by titration is a desideratum. The old method by Mayer's reagent gave good practical results although chemists denounced it as empirical. Recently this titration has been placed on a scientific basis by Dr. Gunner Heikel, and his method certainly deserves the consideration of the new committee.

7. Opium Assay.—The convenient lime process for determining morphine in opium involves of necessity the principle of an aliquot part, and hence it is not likely to find favor with the new committee. The alternative method of precipitating the morphine from a concentrated aqueous solution by ammonia in presence of ether has been very generally accepted, but yields an alkaloid far from pure, and what is of more serious consequence, containing an impurity having an alkaline reaction. Several methods have been proposed for eliminating this troublesome impurity. Perhaps the best of these is precipitation of the concentrated aqueous solution with alcohol. Other plans are to get rid of calcium at the outset by the use of ammonium oxalate, or to add to the concentrated solution a small quantity of ammonia, and filter out the precipitate formed.

Another expedient is to modify the titration process in such a way that the impurity does not affect the result. This may be done by dissolving the crude morphine in an excess of lime water, quantity accurately measured, allowing the insoluble matter to subside, and determining in an aliquot portion of the solution total alkalinity.

These alternative plans for the improvement of the opium assay process should be carefully studied by the new committee, results of the studies of the Association of Official Agricultural Chemists being also taken into consideration. (A. B. Lyons, Chairman.)

OPium Assays—Criticisms.

1. Agitation.—The Pharmacopoeia says "Agitate it every ten minutes (or continuously in a mechanical shaker) during three hours." In my opinion the amount of shaking is of much importance, and certainly shaking every ten minutes during three hours, is by no means the equivalent of shaking continuously in a mechanical shaker for three hours.

2. Transference of the moist Opium back to the flask by means of a spatula.—Most operators find it difficult to transfer all the opium back into the flask by means of a spatula. I find that after the first filtrate has been collected, it is much easier to perforate the filter, and thus transfer the still moist opium back to the flask, completing the transference by washing the residue on the filter back into the flask by means of the 50 Cc. of distilled water prescribed for the second extraction. The third filtrate may be obtained in same manner.

3. Exhaustion of the Drug.—I find that in many instances, where the directions of the Pharmacopoeia have been followed carefully, the drug is still not exhausted. In my opinion, the directions should include the injunction to collect the filtrate until the drug is exhausted, which is to be shown by an appropriate test.

4. Evaporation of the Filtrates.—The Pharmacopoeia directs as follows: "Evaporate
carefully in a tared dish, first, the second filtrate to a small volume, then add the first filtrate, rinsing the vessels with the third filtrate," etc.

The word carefully is in my opinion badly chosen. We all know what a general term means to many people. I think it should be explicitly stated that the evaporation be carried out on a water-bath.

5. Transference of Crystals for Purpose of Weighing.—The Pharmacopoeia states: "Then carefully transfer the crystals to a tared watch-glass, and weigh."

Again the term "carefully." I have noted in some instances that it was difficult to remove the crystals. At other times the operator succeeds in transferring parts of the filter paper to the watch-glass. I have found no difficulty in using counterpoised filters for the double filter used, and in weighing the crystals on the filter.

6. Using Lime Water.—I believe more stress should be laid on the necessity of carrying on the filtration with rapidity, thus avoiding the formation of undue quantities of calcium carbonate. (Geo. C. Diekman.)

I believe that the opium is thoroughly exhausted if the official directions are carefully followed, but I have found it an advantage in the assay of moist gum opium to incorporate the gum in a mortar with an equal weight of dried and washed sea-sand, washing all into the flask. This favors mechanical subdivision and makes exhaustion easy. In the assay of the tincture and deodorized tincture we find it advantageous to evaporate the tincture with the addition of 5 grams of purified talcum. This tends to prevent the precipitation of resinous flakes and facilitates subsequent washing.

Instead of treating the whole of the crude morphine with lime water, I prefer to powder the crude morphine in a small mortar and weigh out exactly 0.5, which is treated with lime water to determine the presence of insoluble matter; then a calculation is made for the whole. Working with this small quantity greater rapidity and accuracy are obtained and a notable quantity of morphine from many assays accumulates for other use.

In relation to titration, instead of washing with lime water, before this is depended upon, it should be determined that the natural lime precipitated with the morphine do not use any of the acid solution.

In the assay of extract of opium the Pharmacopoeia directs that 4 grams of extract shall be dissolved in water to make a total of 15 grams of aqueous liquid, and that this should be mixed with 8.5 Cc. of alcohol, 20 Cc. of ether and 2.2 Cc. of ammonia water. As the amount of liquid is three-fourths that used in the regular assay, and the amount of extract of opium is of official strength, represents only two-thirds the amount of morphine as represented by the amount of opium used in assay, the proper proportions of alcohol, ether and ammonia water are not used. If three-fourths of the liquids used in the regular ammonia-opium assay were used to represent three-fourths the amount of aqueous liquid, the figures would be: Alcohol, 9.15 Cc.; Ether, 18.75 Cc.; ammonia water, 2 625 Cc. This slight change in the character of liquid is not advisable, for it must have some influence on the precipitation of morphine. It would be better to start with 6 grams of extract of opium, which amount would represent the same amount of morphine as 10 grams of official powdered opium; then make the aqueous washings up to 20 grams and precipitate as in the regular opium assay.

The directions on page 145, lines 5 and 6 (for at least six hours, or over night) should be changed to (for at least 16 hours). (E. I. Patch.)

This suggestion for the use of purified talcum in the manipulation of the assay for tincture of opium is in harmony with the recommendation made by Charles Bullock, recommending the use of kaolin for the same purpose. (See American Journal of Pharmacy, 1887, page 127.) I have frequently used kaolin since Mr. Bullock's suggestion. Probably keiselguhr is still better. (George M. Beringer.)
The object sought in the pharmacopoeial description of a drug is simply to render its identification certain and complete. In the case of a definite chemical compound, therefore, such descriptions would be comprehended in a single very short paragraph. Since, however, we depend in practice very largely upon information given us instantaneously by our senses, it is natural and right that in all cases a succinct statement of the sensible properties of the article be included in the description, and there is equally good reason for including likewise its more conspicuous physical properties. This practice in fact is followed by every pharmacopoeia.

Descriptions of sensible properties almost of necessity lack scientific precision, although collectively they often suffice to render identification of a drug quite certain. Physical properties, on the other hand, admit of exact scientific definition, and hence are of greater intrinsic value than sensible properties. The physical properties which are of especial importance are: 1. solubility in various liquids; 2. density or specific gravity; 3. optical properties; 4. congealing and boiling points. These will here be considered briefly in order.

**SOLUBILITY.**

In the great majority of cases approximate statements with regard to the solubility of a drug in the ordinary solvents, particularly in water and alcohol, answer every useful purpose in a pharmacopoeial description. In absence of exact determinations, the degree of solubility may well be indicated by the use of certain adverbs, to each of which should be attached a well defined meaning. A substance requiring for solution more than 200 times its weight; up to 1000 perhaps, would be described as very sparingly soluble; 1:50 to 1:200 as sparingly soluble; 1:16 to 1:50 moderately soluble; 1:8 to 1:16 readily soluble; 1:3 to 1:8 freely soluble; and 1:3 or less very freely soluble. It is better of course to give a definite approximate figure as about 1:75 or about 1:87, the use of the qualifying adverb indicating that some slight variation from the figure given might be expected. It should be explained in the Introductory Notices that the expression soluble in distilled water 1:75 at 20° means that 7.5 grams of a solution saturated at 20° under specified conditions will contain 1 gram of the substance. Only in exceptional cases is the exact degree of solubility of the substance an important criterion of its identity or purity. Here omission of the qualifying adverb “about” indicates that the figure given is authoritative and exact.

**DENSITIES OR SPECIFIC GRAVITIES.**

No physical property of a liquid is more easily ascertained in exact figures than its density or specific gravity. It would seem desirable that in the description of any substance its density rather than its specific gravity should be stated, i.e., the weight in grams of a volume of the substance equal to that of one gram of water at maximum density. It is a little easier possibly to ascertain the specific gravity of the substance, i.e., the weight of a volume equal to that of one gram of water at the same temperature, and hence it is specific gravities rather than densities that are commonly given. The present Pharmacopoeia gives in its specific gravity tables, and likewise sometimes at least in its text, apparent, not true, specific gravities. In other similar publications it is almost invariably true specific gravities that are given. The figures should certainly be changed to bring our pharmacopoeia into harmony with others in this respect. This means that all pyconometer weighings shall be reduced to “vacuum.” A table should be furnished showing the corrections to be made for displaced air, and also the apparent weight at standard temperature of one liter (or 1 Cc.) of water. The question of standard temperature will come up once more, inasmuch as our pharmacopoeia stands alone in assuming as that standard 25° C. While 25° is convenient and rational, the fact must be con-
sidered that the U. S. Bureau of Standards has adopted 20°, which is better than the 15° of continental Europe. If the Bureau cannot be induced to see the advantage of the more radical change (to 25°), we can “compromise” on their standard with some hope that the change will be generally adopted in America.

To sum up; we recommend that in the text of the Pharmacopoeia true densities, standard \(20^\circ\)\text{(vacuum)} be given; in the specific gravity tables, true specific gravities, standard \(20^\circ\)\text{(vacuum)}.

**OPTICAL PROPERTIES.**

In addition to the specific rotatory power over the polarized ray of certain organic substances—a property which enables us to discriminate between substances otherwise closely similar, and often to detect sophistications, the index of refraction of substances, particularly liquids, is a physical property occasionally of great importance. It will be well for the new committee to consider the advisability of including this among the data which should enter into a complete pharmacopoeial description.

**MELTING AND BOILING POINTS.**

The exact method for determining melting, congealing and boiling-points should of course be prescribed in the Pharmacopoeia.

**ATOMIC WEIGHTS.**

In this connection, it is in order to call attention to the fact that the U. S. Pharmacopoeia is quite out of date in adhering to the basis for atomic weights of H=1. Chemists almost universally use the International Atomic Weights, based on O=16, and it is time for our pharmacopoeia to fall into line. The importance of this becomes manifest when we consider that the volumetric solutions of the Pharmacopoeia do not agree in strength with those commonly used in chemical laboratories, or those supplied by dealers in chemicals. The difference is quite appreciable, amounting to three-fourths of one per cent. (A. B. Lyons and L. F. Kebler.)

**OFFICIAL FORMULAS AND PREPARATIONS.**

_Waters._—Instead of having formulas for the various waters requiring 2 Cc. of oil to 1000 Cc. of water a general formula suggesting this proportion should be included, and anise, cinnamon, fennel, peppermint and spearmint dropped, as distinct formulas. (E. G. Eberle.)

_Hamamelis Water._—I think ought to be transferred to the N. F.; at least directions for making should be omitted; few if any druggists make it. In the test the strength solution of salicylic acid ought to be specified, say 1 Grm. in 1000 Cc. (E. G. Eberle.)

_Solution of Hydrogen Dioxide._—Ought to allow for alkalinity (if made from perborates). (E. G. Eberle.)

_Stronger Rose and Orange Flower Waters._—There is no standard of strength for stronger rose and orange flower waters, dilutions would vary, why not simply have orange and rose water official? (E. G. Eberle.)

_Elixirs._—Dissolve the oils in the alcohol, add the water and percolate (?) through sugar. Transfer elixir adjuvans to the N. F. elixir of iron, quinine and strychnine phosphates replace by elixir of iron, quinine and strychnine of the N. F. Have the phosphates as such in this elixir any medicinal advantage over other salts? I doubt it. Introduce the tincture of citro-chloride of iron N. F. (E. G. Eberle.)

_Emulsions._—Drop emulsions. Their place is in the N. F. (E. G. Eberle.)

_Glycerite of Borostylicin._—Omit the formula, only a few druggists make it. (E. G. Eberle.)
Compound Antiseptic Solution.—Would be improved by the addition of a small amount of glycerin. (E. G. Eberle.)

Mucilage of Acacia.—Make fresh when needed by simple solution in water and omit the lime water. (E. G. Eberle.)

Spirits.—My experience is that only few druggists make spirit of nitrous ether. I believe, therefore, ethyl nitrite ought to be official. Have a general formula for making spirits, omit spirit of anise, juniper, juniper compound and lavender. (E. G. Eberle.)

Tincture of Iodine.—The amount of potassium iodide in tincture of iodine ought to be reduced. (E. G. Eberle.)

FLUIDEXTRACTS.

As therapeutic agents, I believe that their importance has been somewhat exaggerated and I would not recommend an increase in their number. Their use is, I believe, a matter of education, and with but few exceptions I believe that the more easily prepared tinctures will answer all requirements. So far as the Pharmacopoeia is concerned, I believe that the details of their preparation can be compassed in a few type processes with great saving of space. I would not favor their preparation by a process based upon incomplete exhaustion of the drug in instances where no standardization is required. I believe that the use of glycerin and acetic acid, etc., should be further investigated with a view to ascertain if after all it is really desirable. I believe that if percolation is recommended as an alternative process, it should be defined. There are several methods of percolation in use, and I do not believe that the results obtained by these different processes will be concordant. Specific instances where its use is desirable should be pointed out. I have found that different lots of senega differ considerably in their tendency towards gelatinization and I have not noted that the present process is any improvement on the former one. I do not know why solution of soda is used in preparing fluidextract of dandelion, unless it is to make sodium salts of its resinous constituents, and I question the advisability of this. I believe that this fluidextract should be made with strong alcohol. (L. W. Havenhill.)

MODIFICATION OF THE OFFICIAL PROCESS.

The instability of fluidextracts is largely due to the extractive in the final exhaustion and the changes that it undergoes in evaporation. A modification that I have tried with aconite and a few assayable drugs is to percolate slowly only 850 Cc. for each 1000 Gm. of drug and take this as the finished product. This was assayed and found to be active and to keep well. If this suggestion is worthy of trial, then in practice the drug might be increased to 1200 Gm. and the percolation carried only to 1000 Cc. (G. M. Beringer.)

FLUIDEXTRACTS THAT ARE GOING INTO DISUSE.

The following are with us scarcely if ever used: lupulin, matico, savin, scopola (never used), staphisagria (tincture only used and strong enough for the purpose), coca, and their dismissal is warranted unless more frequently used elsewhere. (G. M. Beringer.)

Fluidextract of Buchu.—The menstruum should be alcohol. (G. M. Beringer.)

Fluidextract of Cinchona.—To insure the extraction of the drug a small quantity of hydrochloric acid should be added to the menstruum. (G. M. Beringer.)

Fluidextract of Nux Vomica.—My experiments convince me that acetic acid extracts a great deal of gelatinous extractive that is objectionable. (G. M. Beringer.)

Fluidextract of Red Rose.—A small percentage of sulphuric acid should be added to the menstruum to extract the coloring. (G. M. Beringer.)

Fluidextract of Senega.—I have not been satisfied with this made by the U. S. P. formula. It deposits a gelatinous sediment. (G. M. Beringer.)

Fluidextract of Senna.—Is the preliminary treatment with alcohol necessary, or is it
generally followed by the manufacturers? It is extremely wasteful of alcohol, adding very materially to cost. (G. M. Beringer.)

TINCTURES.

Tinctures.—Commenting upon the tinctures, I question the desirability of a uniform 10 per cent. strength. I see no reason for unnecessarily increasing their dose, as this would do. If we are to seek uniformity in the tinctures, why not base this upon the dose? I am not prepared to say that tincture of iodine from the standpoint of efficiency has been improved. It is, however, unquestionably more permanent than the former tincture. (L. W. Havenhill.)

Tinctures from Fluidextracts.—While this may be permissible in a few cases, the great danger is in the abuse. I have reason to know that there are quite a number of druggists and physicians who carry this easy process to the extreme and make such preparations as paregoric, tincture of benzoin and the compound tincture of benzoin from fluidextract, and even fluidextract of asafetida (so called) is sold for the purpose of making tincture and milk therefrom. On several occasions I have been enabled to compare such with U. S. P. preparations and the difference was very marked. Personally I believe that we should in every way possible provide that preparations be made direct from the drug and that much of the present slipshod, lazy work that is so detrimental to the standing of the profession is due to the neglect of this fundamental principle of the pharmacists' calling. (G. M. Beringer.)

Tincture of Belladonna.—Always made from the leaf; omit “Foliorum” in title. (G. M. Beringer.)

Tinctures of Benzoin and Benzoin Comp.—Directions to triturate not practical. Why should this be done in benzoin and not in tincture aloe, etc.? Maceration in suitable container with frequent agitation is sufficient in this as in others. (G. M. Beringer.)

Tincture of Gambir, Comp.—The change to gambir has not proven satisfactory and with us tr. catechu comp. is usually specified possibly also because that was just double the strength of the present official. Why the change here to 5 per cent. tincture? (G. M. Beringer.)

Tincture of Lactuca.—See paper on syrups where this is taken up. If my views on this are adopted there will be no need for the tincture. (G. M. Beringer.)

Tincture of Nux Vomica.—I have tried to make this from a number of the extracts on the market and the results have been all colors and appearances and all precipitated, some very much more than others. For several years now, I have been preparing this direct from the drug, using as a menstruum alcohol 3 water 1. The result has been eminently satisfactory, assaying fully up to the U. S. P. requirements and, on some lots using 10 per cent. of drug, actually above, and kept without any precipitation. In order to be assured of the strength of this tincture even when made from an assayed solid extract the U. S. P. directs assay of the product. I believe that the best tincture is one made direct from the drug. (G. M. Beringer.)

Tincture of Opium.—I believe that the present official method will yield a satisfactory preparation. The time is fully at hand when under the existing conditions the pharmacist must be prepared to assay his own preparations and as tincture of opium keeps fairly well it can be made in sufficient quantity to warrant assay without materially adding to the cost. (G. M. Beringer.)

Tincture of Vanilla.—Here the directions are not plain, and need re-writing to clarify. Instead of "reserved" liquid which might be construed as either the portion of menstruum not used in the maceration or the liquid used and strained off, should say the "strained liquid" and then later on in place of "sufficient menstruum" the balance of the prepared menstruum and then continue percolation with a mixture of alcohol and water of the same proportion until 1000 Cc. is obtained. This example well illustrates
the advantage of a simpler method of specifying alcoholic menstruums as a simple statement that alcohol 160 per cent. was to be used would suffice. (G. M. Beringer.)

*Vin* *tincture of Quillaja.*—If diluted alcohol will extract this for fluidextract then why does the U. S. P. direct the tincture to be made by decoction? 800 Cc. of boiling water will not extract 100 Gm. of quillaja nor will the subsequent displacement with the amount directed suffice. If percolation with hydro-alcoholic menstruum will extract for fluid-extract then is it not also probable that the same menstruum would be preferable for the tincture? This is easily demonstrated by experiment. (G. M. Beringer.)

*Vin* *tincture of Veratrum.*—I doubt the advisability for uniform 10 per cent. drug strength for all tinctures. My experience is that this pharmacopeial experiment has destroyed the confidence of our local physicians in at least one very important tincture, namely, that of veratrum viride. I note a very decided increase in the demand for a certain proprietary tincture and several of my medical friends in answer to my queries have said that their use for this was in eclampsia and that they failed to get results with the official tincture. This may be due to their neglecting to quadruple the dose of the official to correspond to that of the previous revision. But if they do so, then they will have to contend with the increased alcohol counteracting the action of the drug. This leads to a suggestion that there be introduced a concentrated tincture of veratrum viride made 50 per cent. drug strength. (G. M. Beringer.)

Tinctures.—The sub-committee has not found time to answer to its own satisfaction, many of the questions that have occurred to it. The feeling of the members, however, is that the processes should be simplified, that space in the U. S. P. be economized, that the strength of the alcohol used in their preparation be reduced to a minimum, and that the number of processes and multiplicity of details be reduced to the lowest limit. While they recognize that a great deal of time and energy has been expended in evolving the present processes, still there is the firm belief that the expenditure of more time and energy, perhaps of a more concerted type will result in many improvements. It is recommended that a definite strength of alcohol be used in preparing the tinctures instead of the extemporaneous dilutions now in use. The committee has not yet had time to prove to its own satisfaction that the changes contemplated in the formulas will prove satisfactory, yet for the purpose of suggesting ground for co-operative work and if possible eliciting discussion, the following is outlined. In finally deciding upon the merits of any process the consideration should be first to have the tincture possess the therapeutic activity of the drug in a permanent form, and second to so modify the working details of the process as to require the minimum of attention from the operator and a minimum of space in the U. S. P. The following is suggested for consideration and revision:

*Process A. Percolation,* as directed in these formulas consists in subjecting a drug or mixture of drugs, in powder, contained in a vessel called a percolator, to the solvent action of successive portions of a menstruum in such a manner that as it traverses the powder in its descent to the receiver it shall become charged with the soluble portion of the drug and pass from the percolator free from insoluble matter.

When the process is successfully conducted, the first portion of the percolate will be practically saturated with the soluble constituents of the drug. If the quantity of menstruum is sufficient to exhaust the drug, the last portion of the percolate should be nearly free from color, odor, and taste, other than that of the menstruum itself.

*Percolators.*—The shape and size of the percolator should be adapted to the nature and quantity of the drug operated upon. The percolator most suitable for the quantities contemplated in these formulas should be nearly cylindrical or slightly conical and contracted into a narrow neck at the smaller end. This neck should be rather short and expanded at its orifice so that a cork may be tightly wedged into it. The larger end of the percolator should be ground so that it may be tightly covered with a ground glass
plate. A cylindrical percolator is preferred for drugs which do not swell appreciably and when the menstruum is strongly alcoholic or when ether or some volatile liquid is used for the extraction. If the conditions are greatly different from these, a conical percolator (funnel) may be used.

Percolators are best constructed of glass but unless otherwise directed they may be made of any material which is not affected by the drug or menstruum. The size of the percolator should be such that after the drug has been properly packed there will be a space of about 7 Cm. between its surface and the top of the percolator.

Preparation of the Percolator.—Into the neck of the percolator should be fitted a perforated cork bearing a short glass tube. This glass tube, which must not project above the inner surface of the cork, should extend from 2 to 3 Cm. beyond its outer surface and be provided with a closely fitting rubber tube, at least one-fourth longer than the percolator itself. This rubber tube ends in another short glass tube, preferably bent in the form of a hook, whereby it may be suspended so that its orifice shall be above the surface of the menstruum in the percolator. A small tuft of absorbent cotton is pressed into the neck and shoulder of the percolator, to serve as a filtering medium. A few drops of menstruum poured upon the cotton will facilitate the passing through it of the first portion of the percolate which is often very dense.

Preparation of the Drug.—The drug to be percolated should be of the fineness directed in the formula, and perfectly air-dried, when weighed. The required quantity is put into a basin, the menstruum poured on and the mixture stirred thoroughly with a spatula. The quantity of menstruum required for this purpose will vary with the nature of the drug. It should be sufficient to cause the drug particles to adhere when pressed firmly in the hand. The quantities specified in the formula will usually be sufficient. If the moistened powder is lumpy, it should be passed through a coarse sieve. No. 30 powders and those which are finer, require a No. 20 sieve. Coarser powders usually do not require this additional treatment after moistening.

The Process.—The powder is transferred to a sheet of thick paper and the whole quantity poured from this into the percolator, shaken down evenly, and packed firmly, unless otherwise specified, with a plunger of suitable dimensions. The pressure used should be governed by the character of the powdered drug and the alcoholic strength of the menstruum. Strongly alcoholic menstruum as a rule permits a firmer packing of the powder than the weaker. The percolator is placed in position for percolation, and the rubber tube having been fastened at a suitable height, the surface of the powder is covered with an accurately fitting disc of filter paper, held in place with a percolator weight or a little clean sand. Sufficient menstruum is now poured on through a funnel, reaching nearly to the surface of the paper to saturate the powder and leave a stratum above it. If these conditions are accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached in this a height corresponding to its level in the percolator. The percolator is closely covered to prevent evaporation and allowed to stand at rest for twelve hours, in the case of tinctures and 48 hours in the case of fluidextracts. To begin percolation, lower the rubber tube, with its glass end hooked into the neck of a bottle marked for the quantity of percolate to be received. By raising or lowering this receiver the rate of percolation may be increased or decreased as desired.

The Rate of Percolation.—For tinctures it should be from 8 to 15 drops per minute, and for fluidextracts, from 2 to 5 drops per minute.

A layer of menstruum must be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added or the required quantity of percolate has been obtained. The menstruum may be added automatically by inverting a bottle containing the entire quantity over the percolator in such a manner that its mouth may dip below the surface of the liquid. The bottle should be of such shape that its shoulder
will serve as a cover for the percolator. The entire quantity of percolate should be obtained and thoroughly mixed before any of it is dispensed.

Maceration with Percolation. Process B.—This process is adapted to the extraction of drugs in which the solution of the active principles takes place slowly or where the saturated menstruum would be too viscid to permeate the successive layers of drugs in the percolator.

Process.—Introduce the drug of the fineness directed into a bottle and pour over it the volume of menstruum specified in the formula, unless otherwise directed. Cork tightly and macerate for seven days. During the maceration the bottle should be shaken at least three times a day.

When the period of maceration has been completed, transfer the contents of the bottle as completely as possible to a percolator which has previously been prepared in accordance with the directions given under percolators, Process A. (The rubber tube for controlling the rate of percolation may usually be omitted.) Allow the liquid to drain off as rapidly as possible, collecting it in a graduated bottle. If necessary some of the first percolate may be used to transfer the last portions of the drug from the maceration bottle. When the liquid has drained completely from the insoluble matter in percolator, pack gently, if the nature of the insoluble matter will permit of it, and add through it, first the rinsings of the maceration bottle and lastly enough fresh menstruum to produce the required volume of percolate.

Process A.—Modified for the use of glycerin, acetic acid, etc. This modification consists in mixing the supplementary solvent glycerin or acid with 100 Cc. of menstruum. The specified quantity of this mixture is used in percolator. When this mixture has passed below the surface of the drug, continue the process from this point in the regular way.

Process B.—Modified for the use of glycerin, acetic acid, etc. This modification consists in macerating the drug in the supplementary solvent glycerin or acid diluted with sufficient menstruum to make the volume specified. After the maceration the process is completed in the regular way.

Tinctura Aconiti, Tincture of Aconite.
Aconite, in No. 60 powder ....................................... 100 Gm.
Alcohol, 70 per cent., a sufficient quantity to make .......... 1000 Cc.
Process A. Moisten with ......................................... 40 Cc.
Tincture of Aconite should assay by the official process 0.045
Gm. of aconitine in each ........................................ 100 Cc.

Tinctura Aloes, Tincture of Aloes.
Aloes, in No. 40 powder ........................................ 100 Gm.
Glycyrrhiza, in No. 40 powder .................................. 200 Gm.
Diluted alcohol, a sufficient quantity to make ............... 1000 Cc.
Process A. Pack gently.

Tinctura Aloes et Myrrha, Tincture of Aloes and Myrrh.
Aloes, in No. 40 powder ........................................ 100 Gm.
Myrrh, in No. 40 powder ........................................ 100 Gm.
Glycyrrhiza, in No. 40 powder .................................. 100 Gm.
Alcohol, 70 per cent., a sufficient quantity to make ........ 100 Cc.
Process A. Pack gently.

Tinctura Arnica, Tincture of Arnica.
Arnica, in No. 20 powder ....................................... 200 Gm.
Diluted alcohol, a sufficient quantity to make ............... 1000 Cc.
Process A. Moisten with 100 Cc. Pack very firmly.
Tinctura Asafetida, Tincture of Asafetida.
Asafetida, well bruised.
Alcohol, a sufficient quantity to make ......................... 1000 Cc.
Process B. Macerate with 800 Cc.

Tinctura Aurantii Amari, Tincture of Bitter Orange Peel.
Bitter Orange Peel, in No. 40 powder ............................ 200 Gm.
Diluted alcohol, a sufficient quantity to make .................. 1000 Cc.
Process A. Moisten with 40 Cc.

Tinctura Aurantii Dulcis, Tincture of Sweet Orange Peel.
Sweet orange peel, from the fresh fruit in thin shavings and cut
into narrow shreds ..................................................... 500 Gm.
Alcohol, a sufficient quantity to make ............................ 1000 Cc.
Process B. Macerate with 900 Cc.

Tinctura Belladonna Foliorum, Tincture of Belladonna Leaves.
Belladonna leaves, in No. 60 powder .............................. 100 Gm.
Diluted alcohol, a sufficient quantity to make .................. 1000 Cc.
Process A. Moisten with 40 Cc.
Tincture of Belladonna should assay by the official process 0.03
Gm. of belladonna alkaloids in each 100 Cc.

Tinctura Benzoini, Tincture of Benzoin.
Benzoin, in small pieces ............................................ 200 Gm.
Alcohol, a sufficient quantity to make ............................ 1000 Cc.
Process B. Macerate with 800 Cc.

Tinctura Benzoini Composita, Compound Tincture of Benzoin.
Benzoin, in small pieces ............................................ 100 Gm.
Aloes, in small pieces ............................................... 20 Gm.
Storax ................................................................. 80 Gm.
Balsam of tolu ....................................................... 40 Gm.
Alcohol, a sufficient quantity to make ............................ 1000 Cc.
Process B. Macerate with 800 Cc.

Tinctura Calendula, Tincture of Calendula.
Calendula, in No. 20 powder ....................................... 200 Gm.
Alcohol, a sufficient quantity to make ............................ 1000 Cc.
Process A. Moisten with 80 Cc.  Pack very firmly.

Tinctura Calumba, Tincture of Calumba.
Calumba, in No. 40 powder .......................................... 200 Gm.
Diluted alcohol, a sufficient quantity to make .................. 1000 Cc.
Process A. Moisten with 100 Cc.  Pack moderately.

Tinctura Cannabis Indica, Tincture of Indian Cannabis.
Indian Cannabis, in No. 40 powder ................................ 100 Gm.
Alcohol, a sufficient quantity to make ............................ 1000 Cc.
Process A. Moisten with 50 Cc.  Pack very firmly.

Tinctura Cantharidis, Tincture of Cantharides.
Cantharides, in No. 60 powder ..................................... 100 Gm.
Alcohol, a sufficient quantity to make ............................ 1000 Cc.
Process A. Moisten with 35 Cc.  Pack very firmly.
REPORT OF THE COMMITTEE ON UNITED STATES PHARMACOPEIA. 787

_Tinctura Capsici_, Tincture of Capsicum.
Capsicum, in No. 40 powder ...................................... 100 Gm.
Alcohol, 70 per cent., a sufficient quantity to make ............ 1000 Cc.
Process A. Moisten with 35 Cc.

_Tinctura Cardamoni_, Tincture of Cardamom.
Cardamom, in No. 40 powder ...................................... 200 Gm.
Diluted alcohol, a sufficient quantity to make .................... 1000 Cc.
Process A. Moisten with 80 Cc.

_Tinctura Cinnamoni_, Tincture of Cinnamon.
Saigon cinnamon, in No. 40 powder ................................ 200 Gm.
Glycerin ....................................................................... 75 Cc.
Alcohol, 70 per cent, a sufficient quantity to make ............. 1000 Cc.
Process A. Modified. Moisten with 80 Cc.

_Tinctura Colchici Seminis_, Tincture of Colchicum Seed.
Colchicum Seed, in No. 40 powder .................................. 100 Gm.
Diluted alcohol, a sufficient quantity to make ..................... 1000 Cc.
Process A. Moisten with 40 Cc.
Tincture of Colchicum Seed should assay by the official process
0.04 Gm. of colchicine in each 100 Cc.

_Tinctura Digitalis_, Tincture of Digitalis.
Digitalis, in No. 60 powder .......................................... 100 Gm.
Diluted alcohol, a sufficient quantity to make ..................... 1000 Cc.
Process A. Moisten with 40 Cc.

_Tinctura Ferri Chloridi_, Tincture of Ferric Chloride.
Solution of ferric chloride ........................................... 350 Cc.
Alcohol, a sufficient quantity to make ................................ 1000 Cc.
Mix them. Allow the tincture to age in a closely covered vessel protected from the
light, for three months; then transfer it to a glass stoppered bottle, and keep in a cool
place. Tincture of ferric chloride should assay by the official process 13.30 Gm. of anhy-
drous ferric chloride in each 100 Cc. Tests and description to follow if desirable.

_Tinctura Gallic_, Tincture of Nutgall.
Nutgall, in No. 40 powder ............................................ 200 Gm.
Glycerin ........................................................................ 100 Cc.
Alcohol, a sufficient quantity to make ................................ 1000 Cc.
Process A. Modified. Shake down the powder evenly and
compactly, but do not moisten or pack it.

_Tinctura Gambir Composita_, Compound Tincture of Gambir.
Gambir, in small fragments ............................................. 200 Gm.
Saigon cinnamon, No. 40 powder .................................... 25 Gm.
Diluted alcohol, a sufficient quantity to make ..................... 1000 Cc.
Process B. Macerate with 800 Cc.

_Tinctura Gelsemii_, Tincture of Gelsemium.
Gelsemium, in No. 60 powder ........................................ 100 Gm.
Alcohol, 70 per cent., a sufficient quantity to make ............. 1000 Cc.
Process A. Moisten with 35 Cc.
Tincture of Gelsemium should assay by the official process —
Gm. of gelsemium alkaloids in each 100 Cc.
Tinctura Gentiana Composita, Compound Tincture of Gentian.
Gentian, in No. 40 powder ........................................ 100 Gm.
Bitter orange peel, in No. 40 powder .......................... 40 Gm.
Cardamom, in No. 40 powder .................................... 10 Gm.
Diluted alcohol, a sufficient quantity to make .............. 1000 Cc.

Tinctura Guaiaci Ammoniata, Ammoniated Tincture of Guaiac.
Guaiac, in small pieces ......................................... 200 Gm.
Aromatic spirit of ammonia, a sufficient quantity to make 1000 Cc.
Process B. Macerate with 800 Cc.

Tinctura Guaiaci, Tincture of Guaiac.
Guaiac, in small pieces ......................................... 200 Gm.
Alcohol, a sufficient quantity to make ....................... 1000 Cc.
Process B. Macerate with 800 Cc.

Tinctura Hydrastis, Tincture of Hydrastis.
Hydrastis, in No. 60 powder ..................................... 200 Gm.
Diluted alcohol, a sufficient quantity to make ............. 1000 Cc.
Process A. Moisten with 60 Cc.
Tincture of Hydrastis should assay by the official process 0.4 Gm.
of hydrastine in each 100 Cc.

Tinctura Hyoscyami, Tincture of Hyoscyamus.
Hyoscyamus, in No. 60 powder .................................. 100 Gm.
Diluted alcohol, a sufficient quantity to make ............. 1000 Cc.
Process A. Moisten with 40 Cc.
Tincture of Hyoscyamus should assay by the official process 0.007 Gm. of the alkaloids of hyoscyamus in each 100 Cc.

Tinctura Iodi, Tincture of Iodine.
Iodine ................................................................. 70 Gm.
Potassium iodide, in fine powder ............................... 50 Gm.
Alcohol, a sufficient quantity to make ....................... 1000 Cc.
Dissolve the iodine and potassium iodide in the alcohol by circulatory displacement. Tincture of Iodine should assay by the official process 6.86 Gm. of Iodine in each 100 Cc.

Tinctura Ipecacuanhae et Opii, Tincture of Ipecac and Opium.
Tincture of deodorized opium, 1000 Cc. reduced by evaporation in a tared dish on a water bath to 800 Gm.
Fluidextract of ipecac ........................................... 100 Cc.
Diluted alcohol, a sufficient quantity to make ............. 1000 Cc.
Mix thoroughly. Filter after 12 hours, washing the filter with sufficient menstruum.

Tinctura Kino, Tincture of Kino.
Kino, in coarse powder ......................................... 50 Gm.
Glycerin .............................................................. 150 Cc.
Water ................................................................. 150 Cc.
Alcohol ............................................................... 700 Cc.
Alcohol, 7 per cent., a sufficient quantity to make ......... 1000 Cc.
Add the kino to the mixture of glycerin, and water in a flask and heat in a bath of
boiling water with frequent agitation for one hour. Cool to 40° C., replace the water lost by evaporation. Add the alcohol, and finish by process B. Macerate for 24 hours. Preserve the mixture in small well filled bottles.

**Tinctura Krameria**, Tincture of Krameria.
Krameria, in No. 40 powder ........................................ 200 Gm.
Diluted alcohol, a sufficient quantity to make .................. 1000 Cc.
Process A. Moisten with 80 Cc.

**Tinctura Lactuca**, Tincture of Lactuca.
I have been unable to manipulate this formula with any degree of satisfaction. As this tincture is used in preparing the syrup, I hope that some better process can be devised for the latter.

**Tinctura Lavandulae Composita**, Compound Tincture of Lavender.
Oil of lavender flowers ............................................. 8 Cc.
Oil of rosemary ..................................................... 2 Cc.
Saigon Cinnamon, in No. 40 powder .............................. 20 Gm.
Clove, bruised ...................................................... 5 Gm.
Myristica, bruised ................................................. 10 Gm.
Red Saunders, No. 60 powder ..................................... 10 Gm.
Alcohol, 70 per cent., a sufficient quantity to make ........... 1000 Cc.
Process B. Macerate with 900 Cc.

**Tinctura Limonis Corticis**, Tincture of Lemon Peel.
Lemon peel, from the fresh fruit, in thin shavings and cut into narrow shreds .............................................. 500 Gm.
Alcohol, a sufficient quantity to make ......................... 1000 Cc.
Process B. Macerate with 900 Cc.

**Tinctura Lobelii**, Tincture of Lobelia.
Lobelia, in No. 50 powder ........................................ 100 Gm.
Diluted alcohol, a sufficient quantity to make ............... 1000 Cc.
Process A. Moisten with 50 Cc.

**Tinctura Moschi**, Tincture of Musk.
Musk ................................................................. 5 Gm.
Alcohol .............................................................. 45 Cc.
Water ............................................................... 45 Cc.
Diluted alcohol, a sufficient quantity to make ............... 100 Cc.
Triturate the musk with the water added a little at a time, until a smooth mixture is obtained; transfer the mixture to a bottle, add the alcohol, and finish by Process B.

**Tinctura Myrrhae**, Tincture of Myrrh.
Myrrh, in small pieces ............................................. 200 Gm.
Alcohol, a sufficient quantity to make ......................... 100 Cc.
Process B. Macerate with 800 Cc.

**Tinctura Nucis Vomicae**, Tincture of Nux Vomica.
Several tinctures of nux vomica have recently come to my notice which had a pronounced odor of ethyl acetate. Does this tincture develop this odor when made from the extract, or only when made from the fluidextract, what is the explanation of it? Extract of nux vomica is very hygroscopic and I think unsuited in several ways for the preparation of the tincture.
Tinctura Opii, Tincture of Opium.

Granulated opium ........................................ 100 Cc.
Alcohol .................................................. 500 Cc.
Diluted alcohol and water, of each a sufficient quantity to make 1000 Cc.

Heat 500 Cc. of water to boiling and pour on the granulated opium and stir thoroughly, occasionally, until the mixture becomes cold. Strain through muslin expressing the residue; reserve this infusion. Repeat the extraction with portions of 250 Cc. of water until the opium is exhausted. Evaporate the second and succeeding portions of infusion on a water-bath to a soft extract. Dissolve this extract in the reserved infusion and transfer to a calibrated bottle, adding the alcohol. Dilute to 1000 Cc. with water. Mix thoroughly and allow to stand over night. Decant through a filter and wash the bottle and filter with enough diluted alcohol to make the filtrate measure 1000 Cc.

Alternate Process.

Extract of opium ........................................ 62.5 Gm.
Diluted alcohol, a sufficient quantity to make ............ 1000 Cc.

Tincture of Opium should assay by the official process from 1.20 to 1.25 Gm. of crystallized morphine in each 100 Cc.

Tinctura Opii Camphorata, Camphorated Tincture of Opium.

Powdered opium ........................................ 4 Gm.
Benzoic acid ............................................ 4 Gm.
Camphor .................................................. 4 Gm.
Oil of anise ............................................... 4 Cc.
Glycerin .................................................. 40 Cc.
Diluted alcohol, a sufficient quantity to make .......... 1000 Cc.
Process B. Macerate with 900 Cc.

Tinctura Opii Deodorati, Tincture of Deodorized Opium.

Granulated opium ........................................ 100 Gm.
Ether ...................................................... 200 Cc.
Alcohol ................................................... 200 Cc.
Water, a sufficient quantity to make ...................... 1000 Cc.

Process U. S. P. VIII. Deodorize with two portions of ether. Tincture of deodorized opium should assay by the official process 1.25 Gm. of crystallized morphine in each 100 Cc.

Tinctura Physostigmatis, Tincture of Physostigma.

Physostigma, in No. 60 powder .......................... 100 Gm.
Alcohol, a sufficient quantity to make .................. 1000 Cc.

Process A. Moisten with 40 Cc. Tincture of physostigma should assay by the official process 0.014 Gm. of physostigma alkaloids in each 100 Cc.

Tinctura Pyrethri, Tincture of Pyrethrum.

Pyrethrum, in No. 60 powder ............................ 200 Gm.
Alcohol, a sufficient quantity to make .................. 1000 Cc.
Process A. Moisten with 80 Cc.

Tinctura Quassiae, Tincture of Quassia.

Quassia, in No. 40 powder ............................... 200 Gm.
Alcohol, 35 per cent., a sufficient quantity to make ...... 1000 Cc.
Process A. Moisten with 60 Cc.

Tinctura Quillajae, Tincture of Quillaja.

Quillaja in No. 40 powder ............................... 200 Gm.
Alcohol, 35 per cent., a sufficient quantity to make ...... 1000 Cc.
Process A. Moisten with 80 Cc.
REPORT OF THE COMMITTEE ON UNITED STATES PHARMACOPEIA. 791

Tinctura Rhei, Tincture of Rhubarb.
- Rhubarb, in No. 40 powder ........................................ 200 Gm.
- Cardamon, in No. 40 powder ....................................... 40 Gm.
- Glycerin .............................................................. 100 Cc.
- Diluted alcohol, a sufficient quantity to make .................. 1000 Cc.

Tinctura Rhei Aromatica, Aromatic Tincture of Rhubarb.
- Rhubarb, in No. 40 powder ........................................ 200 Gm.
- Saigon cinnamon, in No. 40 powder .............................. 40 Gm.
- Cloves, bruised ....................................................... 40 Gm.
- Myristica, bruised .................................................. 20 Gm.
- Glycerin .............................................................. 100 Cc.
- Diluted Alcohol, a sufficient quantity to make ................. 1000 Cc.

Tinctura Sanguinariae, Tincture of Sanguinaria.
- Sanguinaria, in No. 60 powder ..................................... 100 Gm.
- Acetic acid .......................................................... 20 Cc.
- Diluted alcohol, a sufficient quantity to make ................. 1000 Cc.
- Process A. Modified. Moisten with 30 Cc.

Tinctura Scille, Tincture of Squill.
- Squill, in No. 20 powder .......................................... 100 Gm.
- Alcohol, 70 per cent., a sufficient quantity to make .......... 1000 Cc.
- Process B.

Tinctura Serpentariae, Tincture of Serpentaria.
- Serpentaria, in No. 40 powder .................................... 200 Gm.
- Alcohol, 70 per cent., a sufficient quantity to make .......... 1000 Cc.
- Process A. Moisten with 60 Cc.

Tincture Stramonii, Tincture of Stramonium.
- Stramonium, in No. 60 powder .................................... 100 Gm.
- Diluted alcohol, a sufficient quantity to make ................. 1000 Cc.
- Process A. Moisten with 40 Cc.
- Tincture of Stramonium should assay by the official process 0.025 Gm. of stramonium alkaloids in each 100 Cc.

Tinctura Straphanthi, Tincture of Strophanthus.
- Strophanthus, in No. 60 powder .................................. 100 Gm.
- Alcohol, a sufficient quantity to make ........................... 1000 Cc.
- Process A. Moisten with 50 Cc.
- Process can probably be improved.

Tinctura Toludana, Tincture of Tolu.
- Balsam of Tolu ...................................................... 200 Gm.
- Alcohol, a sufficient quantity to make ........................... 1000 Cc.
- Process B. Macerate with 800 Cc.

Tinctura Valerianae, Tincture of Valerian.
- Valerian, in No. 60 powder ....................................... 200 Gm.
- Alcohol, 70 per cent., a sufficient quantity to make .......... 1000 Cc.
- Process A. Moisten with 60 Cc.
Tinctura Valeriana Ammoniata, Ammoniated Tincture of Valerian.
Valerian, in No. 60 powder ........................................ 200 Gm.
Aromatic Spirit of Ammonia, a sufficient quantity to make .... 1000 Cc.
Process A. Moisten with 60 Cc.

Tinctura Vanilla, Tincture of Vanilla.
Vanilla, cut into small pieces and bruised ...................... 100 Gm.
Sand ................................................................. 100 Gm.
Diluted alcohol, a sufficient quantity to make .................. 1000 Cc.
Macerate the vanilla in 500 Cc. of diluted alcohol for 24 hours, then strain off the liquid, and beat the residue and the sand in a mortar to a uniform mass. Pack this mass in a percolator and proceed by process A, using as menstruum, first the strained liquid, and lastly diluted alcohol.

Tinctura Veratri, Tincture of Veratrum.
Veratum, in No. 60 powder ....................................... 100 Gm.
Alcohol, a sufficient quantity to make .......................... 1000 Cc.
Process A. Moisten with 40 Cc.

Tinctura Zingiberis, Tincture of Ginger.
Ginger, in No. 40 powder ...................................... 200 Gm.
Alcohol, a sufficient quantity to make .......................... 1000 Cc.
Process A. Moisten with 60 Cc.

Tincture Herbarum Recentium, Tinctures of Fresh Herbs.
It would seem desirable to have these of uniform strength, each 100 Cc. of tincture to contain the active principles of 10 Gm. of dry drug.

(L. W. Havenhill, Chairman).

FURTHER COMMENTS ON THE OFFICIAL SOLIDS FOR EXTERNAL USE.

Cataplasma Kaolini is all right when freshly made as called for. It is then not necessary to heat the kaolin.

Cera Flava and Cera Alba are both satisfactory.

Cerates.—Camphor, cantharides and the subacetate of lead cerates made according to the formulas of the 1880 Pharm. are better products than those of the last two revisions. The old and tested formulas of the two resin cerates are good.

Benzoinated Lard.—Made by the formula of 1880 is a more cleanly process than that of the present pharmacopoeia and just as good.

Adeps Lanae Hydrosus.—Should be dropped, the information that adeps lanae has the property of being miscible with water, set out under its description.

Cetaceum is all right.

Mustard Plaster.—The spreading and preparation of mustard plaster is an art of the past and may as well be dismissed (the formula I mean).

Oleates.—Are easily made, and should be retained.

Ointments.—As a class need careful revision. The substitution of white wax for the yellow in recent revisions is a mistake. Ungentum of the present pharmacopoeia is much inferior to that of 1880. The only apparent excuse for this change being a change of color from yellow to white.

Ointments of boric acid, Diachylon, nutgall, nitrate of mercury, iodoform, tar, sulphur and zinc oxide, are all right providing they are made up fresh when dispensed.

Rose water ointment formula is good, and ought not be changed.

The use of glycerin in tannic acid and the iodine ointments is not necessary and should be omitted.
The omission of benzoinated lard from the formulas for belladonna and stramonium ointments would be an improvement.

In the formula for chrysarobin ointment, there seems to be a typographical error, 6 Gms. chrysarobin being ordered instead of 5.

To the formula for mercurial ointment add some wool fat. This will expedite the division of the mercury.

Leave out petrolatum from the white precipitate ointment, and use just enough water to thoroughly rub out the white precipitate. Mixed then with wool fat we get a very smooth and nice preparation.

The dilute blue ointment made with lard or benzoinated lard is superior to that made with petrolatum.

Don't see the wisdom of having both ointments official. That of the red if properly made, becomes the yellow anyway. Cheapness of one chemical over that of the other has been stated, should not receive consideration, which quality of the finished product might be, under careless manipulation, so very inferior.

Ointment of phenol made up with the old yellow wax simple ointment of 1880, is far superior to that made up with petrolatum.

Ointment of zinc stearate made with benzoinated lard will be quite an improvement on the present formula. (Wm. Mittelbach.)

Charles E. Caspari,
A. B. Lyons,
Edger L. Patch,
C. S. N. Hallberg,
L. F. Kuhler,
George M. Beringer, Chairman.

The Chair expressed the hope that, in the discussion on the scope of the Pharmacopoeia, the members would confine themselves to the principle, and not dwell on the individual article, because to do the latter would mean that the Section would have to stay in session all the week. He thought there was ample to say in regard to the principle, without attempting to deal with the individual article.

Mr. Francis said he would like to ask as a matter of information whether this very valuable work in the form suggested was liable to be brought officially or otherwise before the delegates who were to gather at Washington City, and who would very largely decide the policy which would control in the revision of the United States Pharmacopoeia. He said he asked this because he really did not know whether it could be brought before the attention of this assembled body—whether that would be possible. But inasmuch as the policy of revision would be largely decided on broad lines, it might serve some very valuable purpose if the wisdom of this body in some form of expression could be brought to the consideration of the delegates there assembled.

The Chair said that this would be an official message from the American Pharmaceutical Association to the Pharmacopoeial Convention. The Pharmaceutical Association, as one of the members of the Pharmacopoeial Convention, was expected to present to that Convention an official report, suggesting the lines along which the Pharmacopoeia should be revised—
suggesting principles, and suggesting in detail the necessary changes that should be made. It was for this reason that this report this afternoon was of such vital importance—"the most vital thing we will have before us at this session." The Chair said he trusted that the expression of opinion by the members would be sincere and to the point. He thought the Convention would be largely guided, in all probability, by the views of this Association; the Association in the past had yielded a great influence on the actions of the Pharmacopœial Convention, and probably would do so in the future.

Mr. Hallberg said he would like to have a definition of what constituted "recognition." If a considerable number of practicing physicians in various States used a medicine considerably for an extensive period, he would call that recognition. "Recognition" did not mean, as he saw it, that certain medical men regarded it as of value; that recognition meant that it was used by physicians in actual practice to a considerable extent. He believed the proposition could be accepted that the tabulated report which represented prescriptions from all sections of the United States gave a fair idea as to the use of these medicines. He said the committee of which he was a member had made summaries of the first 10,000 prescriptions from different localities, and they had made a summary again of about 40,000 prescriptions, and singularly enough the average was almost the same for the first 10,000 as it was for the total 117,000; the average seemed to hold good throughout. He said this collection represented 8,000 prescriptions from the New England States, 33,000 from the Eastern States, 40,000 from the Central States, 7,000 from the Southern, 11,000 from the Western, 7,000 from the Southwestern, 3,000 from the Mountain and 8,000 from the Pacific States. Mr. Hallberg gave it as his opinion that recognition meant medicines that were shown by this compilation to be used by general practitioners.

Mr. Stevens thought the fact that physicians prescribed a thing did not necessarily make it valuable. Some physicians prescribed a certain preparation once and did not use it again. This was notably so where some traveling man comes to a locality and gets a physician to prescribe a preparation once or twice, and he goes away and that is the end of it. Yet such prescriptions as these get into a compilation like that here presented. He said the thing to bear in mind was the use, not the recognition, of value. Things were put in the Pharmacopœia because there was a demand for them, and not that they were preparations of value. While pharmacists might desire certain things in the Pharmacopœia because there was a demand for them, they did not pretend to say they were valuable. Nothing in the Pharmacopœia had any guaranty of value.

Mr. Beringer suggested that item 2, title, "Function," of the committee's proposed list of general principles to be observed in the revision of the Pharmacopœia, covered this point.
Mr. Kraemer said this was a very important question. There was a movement on the part of the medical profession to determine what should be the additions and deletions in the Pharmacopœia. So far as he knew, the value of statistics of prescriptions had never been brought to the attention of the Committee of Revision, but would probably be brought to the attention of the Convention, and he quite sympathized with the statement made by Mr. Stevens. When a substance had a recognized value, he thought it should go into the Pharmacopœia, whether it was used or not. Whether the reverse of this was true he was not so clear. He expressed the hope that this discussion would continue for a little while, because it was very important to the interests of pharmacists, and when the Convention met in Washington City next week, it was a question of what interest they had in that work. The pharmacists of the country were vitally concerned in the Pharmacopœia, more so than even the medical profession, and he hoped there would be a full discussion on the value and importance of these statistics of prescriptions. He thought that the pharmacists ought to have a hand in saying what substances should be included in the Pharmacopœia and what deleted from it, and that it should not be left entirely in the hands of the medical profession.

Mr. Lyons thought there was danger of misapprehension and misunderstanding on a subject of this kind. He said he thought as he listened to the reading of the report that, on the one hand, there was a certain class of physicians that considered physiological action the only test of value—some demonstrable action; while on the other hand, the great rank and file of the medical profession expressed themselves in their prescriptions. Whether they had definite ideas or not, the prescriptions told what they expected would have a curative effect. He thought this was not the time to debate what would come a little later in the report—the question of the function of the Pharmacopœia, and he doubted the advisability of discussing this subject any further at this time.

The Chair called attention to the recent report of the Committee on Conference of the British Pharmacopœia, an interesting report on some 40,000 prescriptions, in which such a substance as digitalin appeared but three times whereas antikamnia appeared 670 times.

Mr. Hallberg said there had been so many "pronunciamentos" on the scope and function of the Pharmacopœia from a medical point of view, that he would like to take up three or four minutes time of the Section in reading a series of resolutions passed by the Chicago Academy of Medicine on the scope of the Pharmacopœia, which he thought contained some new features and new principles that had heretofore not been presented from any medical society:

CHICAGO, April 21, 1910.

WHEREAS Pharmacopœias have always been merely legal standards for the purity of drugs prescribed by physicians in legal practice of their profession and,
WHEREAS the first American Pharmacopoeia, that of 1778 established by Dr. Tilton, Surgeon General of the Continental Army, was merely a check on drugs, sold by Contractors; and,

WHEREAS this principle is the only one which has determined, justified and secured the existence of pharmacopoeias for centuries in the old world and the new; and,

WHEREAS any departure from this function in the education, uplift or other extra legal direction would destroy the Pharmacopoeia in the courts as a legal standard, since the speculative element would dominate the product of centuries of evolution; and,

WHEREAS this principle of a legal standard of drugs prescribed must be based on statistical study of drugs actually prescribed; therefore, it is hereby

Resolved, By the Chicago Academy of Medicine that only such changes should be made in the Pharmacopoeia as are adapted to secure its function as a legal standard;

Resolved, That all compounds now tested by decades of use should be retained in the Pharmacopoeia and that no sectarian notions as to the use of single drugs should be permitted to control in any way the retention of drugs or compounds in the Pharmacopoeia especially since upon methods of preparation depend therapeutic efficiency.

Resolved, Further, that no article should be dropped from the Pharmacopoeia which statistical study of prescriptions shows to be still in use.

Resolved, That upon statistical study of prescriptions alone can a Pharmacopoeia be based.

Resolved, Also that, since clinical studies of drugs show the existence of idiosyncrasies leading to untoward effects substitutes for drugs are needed in emergencies and that no drugs should be dropped because one drug seems to meet ordinary therapeutic indications.

Resolved, Further, that scientific principles, not parsimonious typography, should govern nomenclature and that dropping of the final $e$ in chloride, etc., and in names of alkaloids is misleading.

Resolved, That whereas the fanatic and the blackleg, the alcophobic and the liquor trust have for different reasons determined to destroy the pharmacopoeic standard of wines and liquors, these in the interest of therapeutic efficiency must be retained, since tinctures will not replace them.

Resolved, That whereas the use of ordinary names leads to self-prescription, therapeutic distrust and drug habits, there should be an extended list of synonyms.

Resolved, That whereas dosage must be determined by emergencies and the state of the patient, no table of dosology should be given in the Pharmacopoeia to serve as a source of malpractice suits.

The Chair asked if there was any further discussion on this question of the scope of the Pharmacopoeia.

Mr. Wetterstroem said he would like to call the attention of the members to the condition of a class of preparations that had been hitherto prepared by a manufacturing house, largely. He referred to the tablet triturates. Heretofore, he said, pharmacists had not been called upon to make any of these, but lately prescriptions were being received of a character that indicated the physicians were not dispensing these tablet triturates as formerly, but were relying on the pharmacists to make them. At the present time some pharmacists were using as a base sugar of milk, others talcum powder, others kaolin, and still others calcium sulphate. He expressed the opinion that some general formula should be embodied
in the Pharmacopœia for a filler for tablet triturates, as the physicians using them did not really know what they were.

Mr. Wood, of Philadelphia, inquired what was to become of the particular section now under consideration; that it seemed there was some difference of opinion as to what the precise wording should be. He wanted to know if the report was to be presented as it stood to the Convention. The Chair replied that, unless the committee was directed to change it, it would stand. Mr. Wood said in that case he would like to move that the phrase, that the committee was opposed to admitting drugs only of recognized medicinal value, be omitted. Mr. Puckner seconded this motion.

Mr. Beringer said he thought Mr. Wood had an erroneous impression of the wording of the report; that the intent of the committee was to state that therapeutic action alone was not to be considered in deciding this question from a pharmaceutical standpoint—not the therapeutic activity of the drug as determined by pharmacological experimentation. He said he thought the language referred to was this: "Equally erroneous is the proposition that the Pharmacopœia shall comprise only drugs and remedies of recognized medicinal value, and that admission should be decided on the basis of established therapeutic activity." He asked what modification of that language was desired.

Mr. Wood responded that his motion was, that the sentence be stricken out, because it seemed to him that, as Mr. Hallberg had stated, thousands of physicians used these things, and the assumption that they had no therapeutic value was a gratuitous insult to the medical profession.

Mr. Hallberg said he would like to ask Mr. Wood who composed the medical profession, the experimenters in research laboratories or the men who went out and battled with disease. In his opinion, the latter constituted the medical profession, not the laboratory workers.

The Chair suggested that this was not the point that Mr. Wood was making, which was, that this particular statement in the report insulted the very men that Mr. Hallberg was defending.

Thos. Stoddart, of Buffalo, N. Y., said he had listened to a number of prescriptions read from the different States, and he wanted to know how many of these prescriptions contained proprietary preparations unknown to the Pharmacopœia; also, as to whether they were prescriptions which had been selected by the committee.

Mr. Hallberg replied that the prescriptions were taken, one thousand consecutively from the files, and without any discrimination. He said there were a great many proprietary preparations from some localities, but a much smaller number than would have appeared five years ago. The results had not been figured out completely as yet, because the compilation was made for the Trustees of the Pharmacopœia, and report would be made next week to the Trustees. The committee was not in a position to go into the details of all these matters as yet, though it had the statistics en masse.
Mr. Beringer said that, after hearing Mr. Wood define his position last week at another meeting, he thought they were not very far apart, and he would like for him to define his position now, and perhaps they could get together.

Mr. Wood said Mr. Hallberg entirely misunderstood him: that his position in this matter was, that as long as a large per cent. of the medical profession were using a drug, and they had used that drug over a considerable period of time, it was *prima facie* evidence that the drug was useful and should be admitted into the Pharmacopoeia.

Mr. Lyons said he would like to offer a substitute to the Wood motion, as he thought if the language was modified there would be a clear understanding of exactly what was meant. Mr. Beringer had used the expression "remedies of recognized medicinal value," but that what he meant was activity—activity determined by pharmacological test.

Mr. Beringer said he thought if this language was changed to "remedies of tested pharmacological value" it would probably meet Mr. Wood’s idea and his own; that he knew they agreed in this matter.

Mr. Wood said he would be glad to accept Mr. Lyons’ substitute, and Mr. Beringer announced he had changed the words to that effect.

Mr. Beringer then read the next section of the report of the committee, dealing with the report of the Sub-committee on Review of Foreign Pharmacopoeias.

Mr. Sondheimer, in regard to the non-compliance of the U. S. Pharmacopoeia with the Brussels Protocol, endorsed the attitude of the U. S. P. as a whole, though some things, such as opium, for instance, needed revision. He thought 10 per cent. of morphine should certainly be adopted in that case. He was very much in favor of the recommendation as to a standard medicine dropper. As all know, the drop is not always a drop, and it would be very dangerous as regards arsenical preparations.

Mr. Lyons commented upon the variance of the Pharmacopoeias of the world from the requirements of the Brussels Protocol, pointing out that the Mexican and Spanish Pharmacopoeias most nearly approximate it, while the German and United States Pharmacopoeias, especially the latter—which represented the greatest independence of thought along these lines, showed the widest variance from the recommendations of the Protocol. The object of the convention was to secure practical uniformity in the strength of important drugs, and in that respect the U. S. P. was the first to enter into the spirit of that idea and adopt the 10 per cent. basis for "potent" tinctures. He said allusion had been made to the difference in morphine strength between the U. S. P. standard and other standards, and called attention to the fact that important differences in the basis of morphine percentages had been ignored.

The international standard for tincture of opium is one per cent. by weight of anhydrous morphine. The U. S. P. standard is 1.2 to 1.25
grams of hydrated morphine (about 1.13 to 1.18 grams of anhydrous morphine) per 100 Cc. of tincture. The difference between the two standards is not nearly so considerable as it at first appears.

Mr. Lyons said there were so many subjects that were embraced in this part of the paper that he did not know how the Section could find time to intelligently discuss them all.

Mr. Hallberg, referring to the classification of the U. S. P. as amounting to only 20-odd per cent. of the requirements of the Protocol, asked if in that was included, as he gathered, that there should be a uniform 70 per cent. alcoholic menstruum for potent drugs. If this percentage rating was based on that idea, he thought it was certainly not fair, and the Chairman was not strong enough in his statement that the U. S. P. had only complied within 20 per cent. of the requirements of the Protocol. He said everybody knew better than to adopt a uniform menstruum of 70 per cent. alcohol for potent drugs. It was ridiculous. No man of experience would entertain such a thing for a moment. "What has the French Codex done?" said Mr. Hallberg. "We have, at the risk of what many thought was a most hazardous undertaking, changed the strength of the tincture ofaconite from 35 to 10 per cent., and of tincture of veratrum viride from 40 to 10 per cent. That certainly was more than any other country has done to conform to this conference held as to potent remedies, and for no other purpose."

Mr. Beringer, said that, speaking of the French Codex, he thought that there was one thing that ought to be explained. The Codex contained in the official list a syrup of iodide of iron, and put after it gallicus and makes it only ½ of 1 per cent.; and then, in order to conform to the Conference, it puts in an appendix the entire Protocol.

The Chair stated that the Codex also included in a footnote the information that, "This is not the International standard."

Mr. Francis said he wanted, if possible, to say something that might emphasize the objection of Mr. Hallberg to the adoption of any class "type process." He believed he was right in the statement that nowhere in the world had the study of liquid preparations reached the development that it had in the United States, and would dislike very much to see the Pharmacopœia take a backward step as a mere matter of expediency, governing the determination of menstrua and process for a preparation. Therefore, the idea governing in all such things should be, to adjust the menstruum after a study of the medicinal constituents of the drug; and also based upon the experience gained by years of preparing and dispensing such tinctures and fluidextracts. Mr. Francis said that there had been accumulated in the United States in the course of the last 35 years, in the manufacturing establishments and by the retail druggist, an enormous amount of practical experience of very great value. Turning to the question of the menstruum of these tinctures specifically, he said the
one criticism that he would offer to the tinctures of the U. S. P., 8th Revision, was that in the main they were somewhat deficient in alcoholic strength. He said he had had considerable experience in the preservation of such tinctures, the keeping and storing of them when made in accord with the last edition of the Pharmacopœia, and he ventured to say that he differed somewhat from the conclusions lately published by a prominent pharmacist to the effect that they were satisfactory. Nearly all of these would precipitate, even when kept under normal conditions: some were better, and some worse. He thought on the whole that a better menstruum would be produced if the alcohol was increased generally. This was especially true of tincture of strophanthus, and tincture of digitalis. The tincture of the latter contained 45 per cent., and the former 70 per cent. of alcohol. He thought in the determination of this matter in the future, pharmacists should be guided, as in the past, by a study of the particular drug under observation.

Mr. Beringer said he thought the statement of Mr. Francis was largely in the line of his own experience. Tincture of strophanthus was certainly a mistake. The results of reducing the alcoholic strength had not been satisfactory. In compound tincture of gentian, the increase of alcohol had not decreased the precipitation, but rather increased it. So he agreed with Mr. Francis that each individual drug should be considered.

Mr. Raubenheimer said he thought the extraction of the fixed oil from strophanthus by ether or petroleum benzin, was a direct violation of the Brussels Protocol. However the resulting deoleated tincture is much clearer and less nauseating.

The Chair suggested that it would also remove the active principle, but Mr. Beringer responded that petroleum benzin would not; that the amount of active principle extracted by this method was very slight—so slight that it could not be estimated.

Mr. Kraemer said that there was no question but that in this country pharmacists were a little wide awake since the passage of the Drugs Act, and he felt that the mistakes that had been made in the past would not be repeated. He referred to the symposium that would be held tomorrow on the pharmacopœias of the world, and said he was sure that there was not a pharmacist in the United States who would not be glad to be informed as to what other countries were doing. In the case of the Netherlands Pharmacopœia, of which he had been rather a close student, he said that the Protocol was incorporated into the Pharmacopœia some nine months before the Protocol was signed by the various countries represented. There was no question but that we cannot readily do all the things as arranged for by the Protocol. For instance, in the preparations of ipecacuanha the bark alone is used and separated from the wood. But, nevertheless, the main point that Mr. Beringer intended to bring out, he thought, was this; That we pledge due consideration to the Protocol, and that the
Revision Committee should, as far as practical, adopt these standards. He said that in the Netherlands Pharmacopœia each one of the international preparations had after its title the abbreviation “F. I.” (Formula Internationale). Again, in that Pharmacopœia, under “cocaine,” the international standards are given. He further suggested that he could not help but feel that the members of the U. S. P. convention were wide awake, and would be perfectly willing to adopt these international standards as far as it was practicable.

Mr. Whelpley said that those who were familiar with pharmaceutical affairs, and particularly with pharmaceutical journalism, extending back 25 or 30 years, would remember the attention the Pharmaceutical Press gave to the subject of an International Pharmacopœia in the early eighties. At that time the pharmaceutical journals published page after page of formulas for the proposed International Pharmacopœia. Those who attended the American Pharmaceutical Meeting in 1892 and '93, would recall the time that was devoted to the discussion of an International Pharmacopœia and the approaching meeting of the Pharmaceutical Congress which was held in Chicago. He thought perhaps some of the members would remember the enthusiasm with which former Treasurer Sheppard figured out that the Association could spare $1,000 for the great and good cause of furthering the publication of an International Pharmacopœia. He saw the Pharmacopœia ready in the printer's hand. But the Congress met and adjourned, and the International Pharmacopœia was no nearer completion than it was the first time the International Pharmaceutical Congress met. Why? Because an effort was being made to give to all countries and agree to everything that country wanted in the Pharmacopœia. In some way, he didn't know exactly how—perhaps the Chairman could explain—pharmacists suddenly became extremely practical, and instead of trying to make an International Pharmacopœia, covering anything and everything that was described in any country, they conceived the idea of this Congress for the unification of potent remedies, in Brussels in 1902, which went to the other extreme, and which was called together principally with the view of agreeing upon uniform standards of strength for arsenical preparations and opium preparations. The other conditions contained in this Protocol were practically the outgrowth of the discussion on arsenic and opium. As the result of that Congress for the unification of potent remedies pharmacists were now working towards an International Pharmacopœia; but from exactly the other standpoint—from the standpoint of each one now vieing with the other country in its effort to agree upon these general standards, where before each country was “standing pat,” and asking of the other countries to adopt their standards. Now they had gone, as Mr. Hallberg had pointed out, to the great extreme of reducing the strength of such potent preparations as tincture of aconite, veratrum viride, and so on, thus showing
their willingness to get together on these things. Mr. Whelpley said he believed there was a lesson to be drawn here, and that a great result could be accomplished if this matter was gone about in the right way. "But we will work a long time if we do not approach the question from the right direction," said Mr. Whelpley. This discussion of the pharmacopoeias of the world also had a high educational value. Mr. Whelpley said they had studied the pharmacopoeias in school several years ago, and they had trouble with it, for the German and French professors preferred to work on some preparations that they knew in their pharmacopoeias when they were students. But to-day, he said, they expect their students to understand a great deal about the principal pharmacopoeias of the world. In other words, pharmacists were broadening their lines of work—their educational status; and at the same time were narrowing down to a common standard of agreement of strength and various other properties of the medicines that were to be used throughout the civilized world.

Mr. Motter said the general point was whether in this country we should to a still greater extent comply with the international standards for these drugs. He said there was one argument which occurred to him which had not been presented. He recalled the argument made by Dr. Horatio C. Wood before the Second International Sanitary Convention, which was published at Washington, when he advocated the translation of the U.S.P. into the Spanish language, looking to the possible preparation of a Pan-American Pharmacopoeia. "Why should we have an international standard?" said Mr. Motter. If the Pharmacopoeia is a book prepared for the convenience of the local medical or pharmaceutical professions, that is one thing. If, on the other hand, a pharmacopoeia is published as a public-health measure—a book which necessarily affects the health of the people at large, and here came in Dr. Wood's argument—in these days of increased and growing transportation facilities, and the growing habit of travel, there is strength in the argument that different countries should adopt a uniform standard, especially for potent remedies, because of the interchange of prescriptions between civilized countries.

Mr. Lyons, upon the proposition of uniform menstruum, said that that subject was thoroughly thrashed out in the Revision Committee, and it was agreed that for each tincture that menstruum should be adopted which experience showed best suited to the drug.

The question of a standard dropper was discussed in all its bearings, and the consensus of opinion was that dosage by drops was not to be encouraged. If the dropper were adopted for use in measuring doses, it would be necessary to determine for each fluid preparation in the Pharmacopoeia the number of standard drops to the fluidrachm—and the physician could not be expected to carry all these data in his memory, as he would be compelled to do in writing extemporaneous prescriptions.

Mr. Beringer stated that that part of the report he was about to read
now was, he thought, perhaps the one most important for the consideration of this Section: He then read the first three sections of the General Principles to be observed in the ninth revision of the U. S. Pharmacopœia.*

Mr. Raubenheimer made the comment on the last section read that what the pharmacist wanted to know, and what the physician wanted to know was what was safe for the public health. That was what all the foreign books had adopted, and it would be adopted here, too, sooner or later "after a number of people have been poisoned."

Mr. Stevens said that, of course, it was absured to have a minimum dose in the Pharmacopœia, but certainly there should be a maximum dose. The Pharmacopœia now had an average dose, especially for potent drugs, so that the pharmacist could see what was a safe dose, and if the prescription went above that he would not dispense it without consulting the physician. The statement should also be made that the maximum dose was not to control the physician, as he might exceed it if he liked. It was simply to be a guide to the pharmacist.

Mr. Hallberg took the position that a maximum dose could not be fixed, because there was no such thing, and a standard could not be fixed for a thing that did not exist. What was a dose for one man was poison to another: one man might take 30 grains of salicylic acid, and would kill the next man. Doctor Prescott had said, "there were no more two human stomachs alike than there were two human faces," and he was right. Say the maximum dose for morphine sulphate, for instance, as given by the Pharmacopœia was one-third of a grain, and a prescription came in for morphine sulphate, one grain, what would the pharmacist do? If he called up the physician, the chances were that he would say that it was none of his business, and would instruct his patient to go to another pharmacist. Another practical and important point was the question of malpractice suits. There was not a month in the city of Chicago that there was not a malpractice suit instituted. A firm of lawyers in that city made a business of getting up such suits. He seriously objected to pharmacists deliberately laying themselves liable to such damage suits.

Mr. Lyons expressed the opinion that they had some good things in Europe after all. For instance, they had an idea there that the life and health of the community were of quite as much importance as the possibility of a damage suit against the druggist or a physician. He thought this was a good idea, and that we needed to have some standard here which would act as a guide to the pharmacist in these cases that occurred everywhere. He ventured to say there was not a pharmacist present who has not had to go to his physician to verify prescriptions. If the Pharmacopœia itself had a standard, the physician would be required to indicate

* See pages 535-546 incl.
on his prescription that he knew what he was doing when he exceeded a certain dose. There was no restriction now, and the physician forgot to indicate this, and the pharmacist ran the risk of a damage suit. He had always advocated some kind of a maximum single daily dose, like the European Pharmacopœias give. It was a sensible idea, and a protection alike to the physician, the patient and the pharmacist.

Mr. Stevens spoke for a maximum dose, and said he did not believe the average dose as it appeared in the Pharmacopœia was of any benefit to anybody. He thought it would have no effect on the question of damage suits, and many people wanted to know what was a safe dose.

Mr. Hallberg said that several gentlemen had asked the question what good the average dose has done in the last Pharmacopœia, and he would endeavor to answer that question: That it was kept constantly before the eyes of the pharmacist, his assistants and clerks, and particularly of the students, this average dose of drugs, and especially of potent drugs. It was the first time there ever had been satisfactory basis for works on medical practice—works on therapeutics, as well as works on pharmacy. It had brought the students to realize what the average dose was, so that they could use due judgment whenever that dose was exceeded in such a way that it might prove dangerous or harmful. Here was a broad basis which had never existed before, and it was especially valuable for the galenicals.

Mr. Seltzer, of Detroit, said that the idea of the average dose in the Pharmacopœia had never appealed to him at all. Every day in filling prescriptions the question came up to him, Has the doctor prescribed too much? What authority had he to look at at the present time? He had the privilege of taking the list of some manufacturing house, which was put out as an advertisement, and looking in that to see whether the dose was too much. He did not believe any doctor could take exception to the pharmacists calling him up in case a dose exceeded the maximum dose in the Pharmacopœia, but he admitted that he might take exception to his calling him up because the dose exceeded the dose shown in an advertising list.

Mr. Hallberg suggested that he would find that in the Dispensatories, but Mr. Seltzer replied that he wanted it in the Pharmacopœia.

Mr. Stevens, replying to Mr. Hallberg's suggestion as to the value of the average dose to the student, said that his experience had been that students paid very little attention to the dose of the ordinary drug, the prescription, and the manner of getting an accurate dosage, and he was decidedly of the opinion that the maximum dose should be in the Pharmacopœia, as a matter of safety to the pharmacist in dispensing potent remedies. He moved, therefore, that this Section recommend that both the average and maximum dose of potent remedies be introduced into the Pharmacopœia.

Mr. C. E. Caspari asked Mr. Stevens if his conception of the average dose was, that twice the average dose would be the maximum dose. Mr.
Mr. Stevens replied, "Not at all"; whereupon Mr. Caspari said that the average dose would not be a true average, then. Mr. Stevens wanted to know what was meant by the minimum dose in constructing the average, anyhow. If the minimum was an uncertain quantity, the average dose would not be midway between minimum and maximum, and, as he had said before, a minimum dose could not be constructed.

Mr. Kraemer said that this was the most intelligent discussion he had ever known on this question, and he believed a sensible conclusion would be arrived at in the matter. He himself was heartily in favor of a maximum dose—a maximum single and daily—with the understanding that if this dose was exceeded the physician should indicate it by a distinguishing mark on his prescription. He believed that it was in the interest of the public to have this maximum single and a daily dose included in the Pharmacopœia. Mr. Kraemer said he wanted the pharmacists to arise and demand their rights on this question. He said that when they went to Washington, there was no question but that the physicians would want the average dose retained, but it was in the interest of the pharmacist that a maximum single and maximum daily dose should also be included in the Pharmacopœia.

Mr. Stevens said he would accept cheerfully this suggestion of a maximum daily and maximum single dose.

Mr. Apple asked where the authority to indicate what the maximum dose should be was to be gotten. He did not think the Section wanted to declare itself in favor of a maximum dose. He was in favor of an average dose as a sort of compromise. He said if there was an average dose there must be an arbitrary maximum dose to base that average on; and who was to determine that? Who was to be the final authority upon the question of a maximum dose, without legal effect? As to the pharmacists rising and demanding their rights, he did not see how they could demand such rights when they were taking away from the medical profession the right to use their judgment as to what they should prescribe.

Mr. Scoville said the question was, not what the doctor prescribed at all—how much. The question was, what was a safe dose. In reply to the suggestion that there was no such thing as a maximum dose, he asked where the doctor stood in that event, if he wanted to give the maximum dose. Referring to Mr. Hallberg's hypothetical prescription calling for a grain of morphine, he asked if there was a pharmacist present that would put that up without questioning it. He wanted to know if there was a pharmacist present who had not had overdoses in his prescriptions. It was oftentimes a delicate question for the pharmacist, and he wanted to draw the line. "We all know that physicians do make mistakes," said Mr Scoville.

Mr. Asher said he thought perhaps this question of a maximum dose did not appeal to all as it did to him. It appeared to be a question of
looking altogether at the matter from the standpoint of the pharmacist, and not giving the physician due credit. Personally, he believed the physicians would accept this maximum dose very kindly. The medical schools were turning out annually hundreds of students whose knowledge of materia medica was acquired in a sort of offhand way, having no guide at all to these doses. By reference to the Pharmacopœia, they would have a guide that would show them how far they could go. This question of a maximum dose was in the interest of both physician and pharmacist, and would be a guide to each. It was not the object here to state to the physician, “You must give so much, and no more;” but it was to be a safe guide to him—a guide which, when he exceeded that limit, would justify the pharmacist in going to him and asking him the question; and no well-meaning physician, when the pharmacist was trying to correct what he believed was an error on his part, would object to that. He thought a little policy on the part of the pharmacist would bring about a proper understanding in this matter.

Mr. Lyons, upon the question of how to know the maximum dose, related an experience coming within his knowledge, where a physician had occasion to give some opium preparation, and went to the Dispensatory and found out that the smallest dose that would kill a patient was three grains, so he prescribed two grains and a half.

The Chair asked Mr. Stevens to state his motion again, and Mr. Stevens replied that it was, that the Pharmacopœia should include not only the average dose, but the maximum single and daily dose.

The Chair stated that the motion was, that the Pharmacopœia should include, in addition to the average dose for all medicaments, the maximum single and daily dose for potent medicaments. Mr. Stevens said this was a correct statement of his motion, and the motion was put and carried.

Mr. Kraemer suggested that there should be a statement in the preface to the effect that the physician might, by a proper distinguishing mark, exceed the maximum dose stated. The Chair said he thought this was understood.

Mr. Beringer read the fourth item in the committee’s statement of general principles, and as bearing on this proposition, also read the recommendation in the present Pharmacopœia as follows:

“It is recommended that changes in the titles of articles at present official be made only for the purpose of insuring greater accuracy, or safety in dispensing. In the case of newly-admitted articles, it is recommended that such titles be chosen as are in harmony with general usage and convenient for prescribing; but in the case of chemicals of a definite composition a scientific name should be given, at least as a synonym.”

Mr. Beringer said that the committee was simply reaffirming that position, with some slight modification.

The item was passed without question.
Mr. Beringer then read the fifth, sixth, seventh and eighth recommendations, relating to botanical names, names for synthetic chemicals, purity rubric, and improved descriptions and definitions.*

Commenting upon the last item read, Mr. Francis asked if the committee meant that there should be included such descriptions as might be necessary to properly identify the substance—in other words, to serve as legal standards for identification. If so, this would involve also the insertion of processes of assay and determination of purity for many substances where such do not now appear. He wanted to know just what was the force of this paragraph.

Mr. Beringer reread the paragraph in question, and said that the reason was that there had been considerable criticism of the pharmacopœial definitions, which had not been prepared as legal standards, and the idea was they should be carefully revised to meet that condition, and the definition should accurately define the commercial product.

The Chair called for further comment, but none was offered.

Mr. Beringer read the ninth item, as follows:

9. Committee on Drug Market: That the Committee on Revision be requested to appoint a special committee to make a thorough investigation of the quality of crude drugs in commerce both in this country and abroad; and to co-operate with the U. S. Government Departments in such investigations, and that this committee be instructed to endeavor to determine the proper limits to variability due to soil and climatic condition or improper handling, and to suggest such improvements as can be introduced in collecting and marketing such wares.

The Chair said that this was a rather far-reaching suggestion, and somebody would have to pay the postage. It was open for discussion.

Mr. Beringer said that a number of drugs were improperly stored, and the committee thought these were matters of proper investigation by the Pharmacopœial Committee, and that the results would be proportionately great.

Mr. Eliel asked if this would have anything to do with oil of peppermint assay. The U. S. Pharmacopœia at the present time required a menthol content of 50 per cent. It would depend very largely on the climatic conditions at the time the crop was harvested, whether the crop would contain such per cent., or more or less. There had been a number of seasons in the last ten years when it would have been absolutely impossible to obtain oil which would come up to the requirements of the U. S. P. and the Pure Food Act. He thought the present menthol requirement was altogether too high for the average crop, and he believed that this criticism would apply to all drugs of this character. It would certainly be a hardship on the druggists of this country to be obliged to comply with the present standard, when it was, as in this case due to causes beyond human control.

* See pages 535 and 536.
Mr. Wood said that there was little doubt in the minds of any one that the Committee on Revision must take into consideration the character of drugs obtainable—the commercial quality of drugs. But on the other hand, it had never been the custom of the Convention to instruct the Committee of Revision as to the manner in which it should do its work, and he did not think it would be good form here to attempt to instruct that committee in such little details. He thought pharmacists might repose perfect confidence in the Committee of Revision, that they would see the necessities of the case and not neglect them.

Mr. Dohme thought the suggestion of the committee was a very good one, as from experience he had found that there were many drugs gathered abroad, as well as in this country, where the gatherers were indifferent, and in many cases ignorant of the correct method and time of gathering and storing these drugs; and it had often occurred to him that it would be proper for some official body to take this matter up and study it, to the end that a better quality of drugs in many cases might be had. In the case of Mexican sarsaparilla, for instance, he said his firm had gotten it with a large amount of inert matter, but when the gatherers were told what they wanted, they proceeded to give them exactly what they wanted. He thought the same was true as to other drugs; they had found as far as Europe was concerned that they had not changed their methods of gathering and storing drugs at the request of the importers of the country. He thought a suggestion of this kind to the Revision Committee, for fear they might overlook it in their deliberations, was timely, and he was very much in favor of it.

Mr. Beringer suggested that all this matter could be carefully investigated, with the view of determining what a good drug was, and the establishment of proper limits. He asked the question as to how a proper standard could be fixed, unless it was possible to determine the rule of variability. He thought the committee could do most excellent work along these lines.

Mr. Lyons thought there could be no question of the great value of acting upon the suggestions here made, but the Pharmacopœial Revision Committee was a body of limited resources, and he did not see how it was feasible for the committee to take such an extensive work as this.

Mr. Wood moved as a substitute that the Revision Committee be requested to take into careful consideration in the effort to establish the purity of crude drugs the quality of drugs commercially obtainable. This would obviate the necessity of instructing the committee how they should go about their work.

Mr. Beringer explained that this was simply a suggestion.

Mr. Raubenheimer seconded the motion just made.

Mr. C. E. Caspari said he believed Mr. Wood misunderstood the intent of the suggestion by the U. S. P. Committee. It was not intended in any
sense to instruct the Revision Committee as to what they should do, but because of the fact that the Pharmacopœia was a national standard, and also that the inspectors of the Agricultural Department frequently found lots of crude drugs which were sub-standard, and the claim made by the owners of these stocks that the market conditions were such that they could not possibly be up to the standard, this suggestion was made. That was the idea, that the Revision Committee, in connection with the government authorities at Washington, could, in the course of perhaps a long time, determine some connection between climatic conditions and the variance in the active principle of drugs. It was not possible for the work to be brought to any satisfactory conclusion by the time the next Revision of the Pharmacopœia was published, but it could do a valuable work, and by the time the following revision was ready to be published a considerable amount of data might be had on the subject.

Mr. Kebler said he thought it was the intent of these recommendations to simply suggest, to give the ideas of this Section as to what was desirable. "How are we going to regulate the countries abroad which collect these drugs?" said Mr. Kebler. He took the case of belladonna-root for illustration, which was excluded if below a certain standard of mydriatic alkaloids. The importers took the matter in hand and advised dealers abroad of the standard, with the result that there is no longer any trouble with belladonna-root.

Mr. Kraemer said he thought the object of this report of the Chairman was merely to authorize his committee, in co-operation with the large dealers and with the government officials, to see that the Committee of Revision had information which would enable them to determine whether, for instance, this year or any year, jalap has a certain content of resin, or again, if catechu can be obtained of standard quality. As a matter of fact, Mr. Kraemer said he did not think these conditions varied as much as might be imagined. If the committee had the proper information, it might establish standards that everybody could conform to, and that drugs of the required efficiency would be supplied.

Dr. Wood said his motion was, that the Revision Committee, in establishing standards, should very carefully consider the quality of drugs commercially obtainable.

Mr. Francis wanted to know if there was any reason for that motion, and if the Pharmacopœial Revision Committee was not to be presumed to be composed of members of common sense, to do just that thing. Mr. Beringer suggested that it would be desirable to hear from Mr. Rusby on this subject.

Mr. Rusby said he was sorry that he was not present to hear the discussion. He thought it might be well, before discussing this question, to say to the Section that there had just arrived from Washington City a very remarkable collection of plants and he directed special attention to the dis-
play of such living plants in the anteroom of the convention hall, where numerous specimens of interesting drug plants were assembled.

Mr. Rusby went on to say that no one was able, under the conditions of the present day, to take a sample of balsam Peru and say whether it was adulterated, because there was not a single specimen available with such perfect record of collection and preservation as to absolutely prove its purity; hence we are forced to base our standards on specimens of the character of which we are uncertain. He said that the conditions as to balsam copaiba were not as bad. What should be the standard for balsam Peru? After struggling with that question for three years, at the port of New York, he was convinced that we would never be able to get a standard for that until somebody went to the place where it was produced and studied its collection and preparation. Last fall Mr. Rusby, when he was going down to Mexico, expected to be in a region where he could study sarsaparilla, vanilla and jalap. He said the reason we now have jalap with 7 per cent. of resin, whereas it used to contain 18 per cent. or more, and below that it was regarded as very poor, required investigation. Now it could not be gotten beyond 7 per cent., and sometimes only 5. Nobody seemed to know, also, what caused the warts on vanilla beans. He believed that it was the duty of the Revision Committee to provide for such investigations as these. Digitalis constitutes another case of the same kind. If it has become a little heated and musty in drying it loses much of its properties. The importers claim that this is unavoidable and that no better drug is obtainable. The question was, What were the conditions on the other side? If good digitalis leaves could not be gotten under any condition, there was no use in fixing a standard. This was one of the most important things the Association could turn its attention to. It should be ascertained whether a drug could be gotten to meet a certain standard; and if not, the standard should be changed. Many of these questions cannot be answered except by studying the drug in its own home, and this is a proper duty for the Revision Committee.

Mr. Hallberg said it seemed to him that Doctor Wood’s substitute motion was not very specific; that he objected to the original, in that it appeared to be a little bit dictatorial. He asked why not combine the two, and modify the original so as to make it a suggestion, leaving the matter of the committee for the consideration of the Convention, so as to make it read that it was suggested that the Committee on Revision make a thorough examination, in connection with the Consular Service and other Government Bureaus, into this matter, and formulate a standard for these drugs. He said he offered this as a suggestion.

Dr. Wood said he would be pleased to accept the amendment.

Mr. Rusby said he hoped Mr. Hallberg would withdraw his suggestion to the U. S. P. Committee. He said the Consular Service of the U. S. would not take the trouble; that a consul would get some Indian to do
the work for him, and there was no dependence on them at all. The material thus obtained would not be authentic or reliable.

Mr. Beringer re-read the ninth item in the list of recommendations.

Mr. Apple commented upon the fact that in the item read the word "instruct" was used in connection with the special committee to be appointed. The Chair said the suggestion was, that, after the Revision Committee had been requested, they should instruct the sub-committee.

The Chair stated that if Doctor Wood did not object, the Section would pass on to the next recommendation.

Mr. Kebler said that, before passing the recommendation just read (No. 9), he wanted to say a few words. He did not know the author of that resolution, but he thought it was a good one. A number of years ago they were confronted with that proposition, and they were not out of the woods yet. After going over the matter, with Doctor Wiley, he appointed a committee to consider the various features that confronted them in their work under the Pure Food and Drugs Act. It was found that of the large number of herbarium specimens in the National Museum, collected by various botanists most of them were undoubtedly correctly named, but only in comparatively few instances had the specimens been verified by specialists so as to remove reasonable doubt. The institution knew that, and had told them plainly that these specimens were put there under these conditions. So, in order to make them available for positive work it would be absolutely necessary that the various groups be referred to a suitable monographer. It was decided by the Committee and agreed to by the Smithsonian Institute to have a place reserved in the National Museum for the storing and keeping of specimens of that character. The Smithsonian Institute furthermore agreed to use its representatives in the field to assist in all of these matters. It is a tremendous job, but that was the only way there would ever be a basis for action. They were trying to adjust the situation as rapidly as possible. Just as soon as the new building of the Museum was completed, they expected to have a room there for the especial storing and keeping of these authentic specimens for future reference. Mr. Kebler said they invited the aid of the Bureau of Plant Industry, the Smithsonian Institute or any one qualified in a special subject, be it botany, chemistry, medicine or what not.

Mr. Beringer, in this connection, called attention to Mr. Rusby's recent article on the amount of adulteration in foreign drugs.

Mr. Beringer then moved the adoption of Section 9 of the recommendations as read, and the motion prevailed.

Mr. Beringer read the tenth and eleventh recommendations, referring to standards for crude drugs and standards for powdered drugs.*

The Chair said this was rather a far-reaching proposition, and asked if there was any objection to it, but none was indicated.

* See page 536.
Mr. Beringer read the 12th, 13th, 14th and 15th recommendations.*

The Chair stated that the last recommendation read, relating to time-limit on drugs, was a far-reaching one, and asked if there was any objection to it.

Mr. Raubenheimer said there were some preparations where there was no deterioration. Mr. Beringer responded that they had qualified that by saying "drug and preparation."

The Chair stated that the suggestion had been made to qualify the recommendation by adding "preparations." He asked if there was any other suggestion, but none was offered, and the section was passed, with the amendment indicated.

Mr. Beringer read the 16th and 17th recommendations, relating to fineness of powders and powdering of drugs.†

The Chair said this would include ipecac.

Mr. Beringer read the 18th recommendation:

18. Synonyms: That the proper English name under which the article is commonly sold be given along with the Latin title of each drug and preparation, and that a list of less important or less frequently used names be published with the other tables as a table of synonyms.

Mr. Wetterstroem gave it as his opinion that a list of synonyms would cause a great deal of trouble in some of the States. He said they had all sorts of trouble with this proposition in Ohio, until they succeeded in getting the law changed in 1906. He reminded the members of the successful effort made at the Pharmacopœial Convention of 1900, in Washington City, to change the Pharmacopœia in this respect, and be hoped the same would be done in the next Pharmacopœia. His idea was that if synonyms were to be given, they should be limited to medicinal substances only, and that no synonym should be used that indicated the commercial name of a drug. In response to an inquiry by Mr. Raubenheimer as to camphorated oil, Mr. Wetterstroem replied that was a medicinal substance, and a synonym would be all right in that case. But there were other substances, such as turpentine and lime, and things of that kind, that were common names, and if they were included in the Pharmacopœia, the pharmacist would be compelled to see that they came up to Pharmacopœial standards.

Mr. Beringer said that the provision of the present Pharmacopœia was limited to the sale for medicinal use.

Mr. Cliffe said that in Pennsylvania the fact that camphorated oil was not a synonym in the Pharmacopœia for Liniment of Camphor had been set up in a defense in a case where a prosecution was brought, where the oil contained from three to five per cent. camphor. The gist of the defense was, that camphorated oil was not a pharmacopœial product.

* See page 537.
† See page 537.
Mr. Kraemer gave it as his opinion that there should be a table of synonyms as an appendix to the Pharmacopoeia.

Dr. Wood said he wanted to remind the members that the National Food and Drug Act said any substance sold under a name recognized by the Pharmacopoeia, and it seemed to him that, even if a table of synonyms was placed in the appendix, it would be taken as found in the Pharmacopoeia, and he thought Mr. Wetterstroem's position was well taken.

Mr. Kebler remarked that the Pharmacopoeia covered only medicinal drugs.

Mr. Beringer said that the Pure Food and Drugs Act also specified that the nomenclature of the National Formulary was to be used.

Mr. Eliel said that, as to sulphuric acid and hydrochloric acid, he knew that certain retail pharmacists sent orders to their jobbers for such things as they had been in the habit of purchasing and using for medicinal purposes, such as Epsom salt, carbonate of magnesia and other things, and the jobber marked these goods "Technical," and the druggist would then use them in his prescription work. He knew this to be an actual fact, and he thought that there should be some way of making a distinction and preventing a thing that was shipped to be used for technical purposes from being used for medicinal purposes.

The Chair asked Mr. Wetterstroem if he objected to Item 18 as read, and he said he would let it stand.

Mr. Beringer read the 19th, 20th, 21st, 22d and 23d recommendations of the committee, referring to General Processes, Descriptions of Galenicals, Sterilization, Atomic Weights, and Structural Formulas.*

The Chair remarked that structural formulas had not been given, although some attempt had been made in that direction.

Mr. Dunning commended the introduction of structural formulas into the U. S. P. as being helpful to the pharmacist in understanding the character of many chemical formulas. He did not think structural formulas should appear in the U. S. P. because they appeared in the French Codex, but said he would like to hear some discussion on this subject.

Mr. Raubenheimer remarked that structural formulas were in the U. S. P. Pharmacopoeia before they were in the French Codex.

Mr. Asher said he believed that structural formulas should be given, but only for all the organics.

Mr. Kremers said this was a very important subject, and was inclined to think the Section should not go on record one way or another on this question. He would not like to see the Association go on record as against structural formulas, particularly at that time, when so few were present to discuss the question. He thought there were so many good things before the Section to discuss that it might be advisable to leave this out.

* See page 538.
Mr. C. E. Caspari said he was one of those who were partly responsible for the introduction of this recommendation, and the chief reason why he opposed the introduction of structural formulas for chemical compounds in the Pharmacopoeia was because he considered that there were many far more reliable sources for the structure of formulas than the Pharmacopoeia. If the pharmacist wanted to get a reliable structural formula, let him get some reliable chemical work and obtain it. Another reason for not publishing structural formulas was the amount of space required to set them out. For instance, in the case of camphor, it would take nearly half a page to publish the structural formula, and the same was true of a good many other substances.

Mr. Kremers said he was perfectly willing to defer to Mr. Caspari's views in the matter.

The Chair said he thought the members understood the position taken here, and that the Section should proceed to the next recommendation.

Mr. Beringer read the 24th item in the list of recommendations:

24. Discriminating Tests for the Druggist: That the simplest identification tests for the needs of the pharmacist be stated first in the list of tests, and be in special type.

Mr. Francis asked what this section meant, and Mr. Beringer replied that it furnished the pharmacist with a simple identification test.

Mr. Turner, of Philadelphia, asked if this meant that the pharmacist would have to apply the same test for purity that the wholesale dealer and the manufacturer did, and the Chair replied in the negative, saying that this was to give the retailer an identity test he might apply. Mr. Turner said that he thought, in testing for purity the same test should be applied no matter who tested it.

Mr. Beringer read Items 25 and 26 of the committee's recommendations referring to official methods for Physical Constants and Chemical Determinations, and Normal Temperature.*

The Chair said this question was open for discussion but as none was offered, the section was passed.

Mr. Beringer read the 27th and 28th recommendations of the committee; referring to Definition of Admitted Impurity and Distinction between Medicinal and Technical Substances.†

Mr. Wetterstroem asked for information whether that phrase just referred to had ever been passed on by the court. He said the reason he asked this was because the Government had taken up the question of turpentine and the question of alcohol, and it seemed to him that perhaps that phrase in the preface of the Pharmacopoeia could have prevented this and similar instances. He said it had prevented the commissioner

* See page 539.
† See page 539 and 540.
in his state from doing anything of that kind, when they had called his attention to it. But if the Pharmacopœial text was adopted as the legal standard, the question was whether the effect of that was to adopt the preface and index, or the whole book from cover to cover, or just the Pharmacopœia proper.

The Chair made the suggestion that perhaps Mr. Kebler, of the Drug Laboratory, could answer this question, as to the force and effect of that phrase in the preface of the Pharmacopœia in regard to the standard for purity and strength—whether it would become operative only when drugs were sold as medicine, or whether it had any force at all; and if so, why turpentine was taken up.

Mr. Kebler responded that if it was clearly established that the article was not intended for medicinal purposes, it was not subject to this law. He said the law stated plainly what a drug was, and it could not be gotten around. For fear of a misapprehension, in the National Formulary it was decided to leave out the appendix. In the preface of the National Formulary it was specifically stated that the appendix was not a part of the N. F.

Mr. Beringer read the 29th and 30th recommendations of the committee referring to weights and measures, and Alcohol Content.*

Mr. Francis, commenting on the recommendation as to alcohol content, said that, in accordance with the law at the present time, all medicaments that were put on sale were required to bear on the label a statement of the amount of the alcoholic content, and this section required that the Pharmacopœia should contain under the description of each article a statement as to the proper alcoholic content. He said that unless a considerable amount of judgment was exercised in allowing a sufficient margin of variation for maximum and minimum, there would be piled up a lot of trouble for the retail druggist. The manufacturer could easily standardize his fluidextracts to a variation of one per cent. above or below the amount stated on the label. But the retail druggist, he predicted, would find it a pretty complex problem, and a very expensive process, to adjust this within one per cent. of the standard given in the Pharmacopœia. There would be an element of danger, therefore, unless there was allowed a reasonable variation in regard to the alcoholic content. It might not be embarrassing to the large manufacturer, but it would be very embarrassing to the small maker.

Mr. C. Caspari, Jr. responded that this point had come up in the committee, and the gentlemen on the committee were well aware of the necessity for making a margin of variation above and below the standard to be fixed, and that margin to be 5 per cent. above and five below the actual amount fixed by the Revision Committee, which would allow a variation of ten per cent. in the product. For instance, where a 60 per cent.  

* See page 540.
alcoholic strength was required, it might go up to 65 per cent., or be as low as 55 per cent.

Mr. Francis said that this idea carried out, in a measure, his recommendation that a fair margin of variation should be allowed.

Mr. Beringer stated that this completed the reading of the 30 specific recommendations or list of general principles which the committee had proposed, and that they had all been adopted without change. The Chair, in answer to a question by Mr. Dohme, confirmed this statement.

Mr. Dohme stated that the suggestions made covered such a wide scope, and were of such great importance to the manufacturer and the retailer and the jobber, and it was so difficult—in fact, practically impossible—for the ordinary individual to appreciate what they really meant by a casual hearing, especially when not accurately heard, that before the Section went on record as adopting all these recommendations as a whole, it seemed to him the members should have a chance to read them carefully and consider them. He moved, therefore, that the section accept the report of the committee, and that it be printed by the committee before adoption.

The Chair responded that the proposition was, that this report was to go to the Pharmacopoeial Convention next week at Washington, and it would be impracticable to have the report printed, circulated and considered before the 10th of May. He suggested that some modification of the motion might be in order; that the report might be considered as a tentative report—be tentatively adopted, subject to revision after further consideration.

Mr. Kraemer agreed with Mr. Dohme that the report was a very extensive one, involving a great many interests, and moved as an amendment to Mr. Dohme's motion that the report be sent to the Revision Committee as an expression of the views of this Section.

Mr. Kebler, also, agreed with Mr. Dohme, because he realized the situation fully. He thought that the reading of the brief presentation that had been made before the Section did not give the members an opportunity of digesting it properly. He knew from experience that frequently by reading over a thing casually it seemed to be one thing, while after careful consideration it was found to be quite another. But he thought that Mr. Dohme must appreciate that this information was simply for guidance, and was not binding, and for that reason did not think it warranted delaying the matter until it was published.

Mr. Patch supported the motion of Mr. Dohme. He said he believed this was a very important matter, and ought to have very careful consideration at the hand of every member of this Association—not alone of those who were present before the Section, but of many able members who were not present. He thought this report should be printed and circulated, and action deferred to the last meeting of the Section, when it might receive more careful consideration.
The Chair again expressed the opinion that this proposition was impracticable, and suggested that the report be accepted and sent to the Pharmacopoeial Convention simply as a report of the Committee. Responding to a question by Mr. Dohme as to whether this meant that adoption by the Association would not be asked, the Chair said he hardly thought it would be fair for the Association at large to adopt it. He thought the report should be accepted for transmission to the Pharmacopoeial Revision Committee. The Committee here was a committee of this Association, and necessarily the committee must be empowered with certain rights and prerogatives, and trusted to do their work as best they knew how. It would be rather presumptuous, he thought, for the Section to adopt all these recommendations, especially in view of the small number of members present at this time.

Mr. Dohme agreed to the amendment of Mr. Kraemer. If this set of general principles was adopted by the American Pharmaceutical Association and handed to the Revision Committee it would undoubtedly have a great deal of weight with that body and he thought before that was done these recommendations should be printed and distributed and receive very careful consideration at the hands of the members.

Mr. Kraemer, speaking further on this proposition, expressed the opinion that the Section should adopt the list of general principles as read and discussed; that mimeograph copies of same should be prepared for the use of members, and the subject be presented to the Association in general session for final approval and transmittal to the Pharmacopoeial Convention. He thought the report should have the backing of the Association itself, otherwise it would go as the work of individuals.

After some further discussion, participated in by Messrs. Beringer, Dohme, Kebler, Sayre, Eliel and Patch, this suggestion of Mr. Kraemer was concurred in as the sense of the Section, and the list of general principles as read was adopted and referred to the Association in general session.

Mr. Francis said he wanted to impose upon the good nature of the Section long enough to say that he thought they should include as perhaps a final recommendation something to this effect: "That in view of the legal status of the U. S. Pharmacopoeia, wherever a substance was included in this authority there should also be appended under each substance, where possible, a practical and accurate description, test or assay, which would enable one to test the quality or strength of the drug." He asked what was the use of having legal standards for a large number of substances for which no tests were provided. The Pharmacopoeia was devoid at present of such tests in many cases.

Mr. C. E. Caspari said he thought this was covered by section 27; that wherever the purity rubric was given, a method was given at the end for determining whether the substance was up to the standard. For example,
copper sulphate, he thought, was required to be 99 per cent. At the end of the description of copper sulphate would be a test to determine that fact.

Mr. Beringer reread Item 27 as bearing on this proposition, and he and Mr. Caspari agreed that this point was covered.

Mr. Francis said if the committee was satisfied that that point had been covered he had nothing further to say; but he thought that all recognized the failure of the Pharmacopoeia at the present time to give definite tests. It was a legal authority, without provision in many instances to make a test.

Mr. Eugene Selzer, of Cleveland, Ohio, seconded by Mr. Wetterstroem, moved a special vote of thanks to the Committee on U. S. P. for the excellent report they had presented, and this motion was put to a vote and carried.

On motion, the Section then adjourned.

**Adjourned Session—Thursday, May 5, 1910.**

The Section on Scientific Papers was called to order at 10 o'clock a. m., by Chairman M. I. Wilbert.

**The Chairman:** President Rusby has requested that we adjourn promptly at 12 o'clock, as the general session will be held at that hour; and as we have a lengthy program before us this morning, we had better get at it at once. So if the readers of the papers do not mind, we will take up the program as printed. The first paper is by Dr. Lyons, and as he is not here, we will proceed to the second paper, entitled “Comments on the Assay Methods of the U. S. P.”, by Mr. W. L. Scoville.

Mr. Scoville then presented the following paper.

**SOME COMMENTS ON THE ALKALOIDAL ASSAY METHODS OF THE U. S. P.**

*By Wilbur L. Scoville.*

The purpose of these comments is not to find fault with the official assay processes, nor to critically analyze all the processes for drug assay in the Pharmacopoeia, but to give voice to some personal preferences in methods of work, and to suggest some changes, minor in importance or otherwise, that may be helpful.

First—Some general considerations.

In most of the processes where a liquid is evaporated to dryness in order to get rid of the alcohol, and to get the preparation in shape to extract its alkaloids with an ethereal or chloroformic liquid, evaporation is conducted either with or without sand. Then the residue which adheres to the dish is directed to be dissolved in, or rinsed with, the chloroformic or ethereal solution—which is impracticable. These residues are not soluble in chloroform or ether, and hence are not rinsed thereby. They
are all softened by, and partially soluble in, the alkali which is to be used in the next step of the process, and the dish can be thoroughly cleansed of its extractive by the alkali and water. So ammonia water or bicarbonate solution is an easier and more effective menstruum to transfer the residue to the ethereal or chloroformic solvent.

Sand is not a good absorbent, and therefore fails of its chief purpose. Sawdust is much better, leaves less residue adhering to the dish, and produces a powdery instead of a lumpy mass to extract. I have never felt the necessity of preparing the sawdust by washing with alkali or ether, then with acid and drying. Ordinarily, carpenter’s sawdust, just off the floor, will serve every purpose.

The next general step is extraction of the alkaline ethereal or chloroformic solution with acid. Sulphuric acid is directed in every instance, and in normal volumetric solution or dilutions thereof. But hydrochloric acid is better in some cases (Cinchona, Coca, Physostigma), because it removes the alkaloid more rapidly. Why not use it? the results are the same.

Then the very weak acids are prone to emulsify, sometimes much too easily. Stronger acids may be preferable for this reason. Physostigma is particularly troublesome, and I prefer to use ten per cent. hydrochloric acid for each shaking. It conduces to peace of mind and cheerfulness as well as to facility in results.

Emulsions are the irritating factors in alkaloidal assays. I have often succeeded in breaking an alkaline emulsion by a liberal use of solid potash, carbonat, and an acid emulsion by strong acid. "Similia similibus curantur," but not in homeopathic doses.

The use of stronger acids also results in some cases in keeping the total quantity of liquids used down to a minimum. Aside from the question whether a moderately strong acid combines more quickly and completely with the alkaloids, the quantity needed for each shaking is smaller because emulsions are less liable to form. And the smaller the quantity of one liquid, the less is required of the next immiscible solvent for the subsequent extraction. So a 5 per cent. acid may be much quicker than a 1 per cent. or weaker.

A third general consideration is that when a fluid extract or tincture is evaporated to drive out the alcohol, then mixed with a dilute acid and filtered, as in the assay of fluid extracts of aconite, ipecac, etc., the addition of a clarifying agent is always advisable. It not only insures a clear filtrate, which is doubtful without it, but it prevents the clogging of the filter, which is likely to occur without it. Talcum, kaolin, infusorial earth or paper pulp, are each suitable. This step should then be continued until the filtrate gives no reaction with Mayer’s reagent.

Finally, a word about the complete extraction of alkaloids from aqueous or ethereal solvents. The general directions are to continue shaking with
the immiscible liquid until the aqueous solution, made acid, if necessary, gives no precipitate with Mayer's reagent. Butaconite, coca, ipecac and some others contain alkaloids which are not easily soluble in ether, and are not intended to be included in the assay.

So with these drugs it is impracticable to test the aqueous solution. Nux vomica also continues to respond to Mayer's reagent after all the strychnine is removed. Such drug assays must have the test applied to the residue obtained by evaporating a small amount of ethereal or chloroformic solution, after dissolving this residue in a drop or two of weak acid. Coniine is much more sensitive to Wagner's than to Mayer's reagent, and caffeine responds to iodine solution, in acid solution, but not to Mayer's.

Thorough shaking is also necessary before the test is applied. This seems so obvious as to make attention to it superfluous, but I have reason to believe that insufficient shaking is often the reason for low results reported. In one or two instances the Pharmacopoeia directs the shaking to be continued for one or two minutes. It were better if all shakings were to be directed to continue two minutes. Solution is not an instantaneous process, and in drug assays it takes effect mostly during the shaking. Hence three portions of solvent thoroughly shaken for two or three minutes each, may accomplish as much as five or six portions with short agitations on each. In this work the rule to "make haste slowly" well applies.

_Aconite._—The chemical assay ofaconite has been much criticised, but that the method of the Pharmacopoeia has a real value can scarcely be denied. It could well be supplemented by the Squibb physiological test, which would add much to its value. The physiological test would be best applied to the drug-percolates or extract, and also checked by two or three observers, since individual susceptibility varies (in the same individual), and the test is so quickly made. The drug and fluid extract should respond to a dilution of not less than 1 in 800, and the tincture at not less than 1 in 80.

In the chemical assay, it is well to weigh the alkaloidal residue before titrating, because the tendency on this assay is to read the end-reaction too quickly. When one gets more alkaloid by titration than by weighing, as may easily happen, the warning can be immediately heeded. Or it may be that most of the active aconitine has decomposed into the antagonistic aconine, of lower molecular weight and higher titrating value. A re-reading of the end point in titration, and supplemental physiological test, will together solve the problem for practical results. In the assay of the fluidextract, a clarifying agent is necessary for the first filtration.

_Belladonna, Hyoscyamus, Scopolia and Stramonium._—The processes for the drugs are satisfactory when a careful use of Mayer's reagent is used to insure complete extraction. On the preparations, the process is all right if the preparation is fresh, but, as pointed out in another paper ("The
Keeping Qualities of the Alkaloidal Fluid Extracts and Tinctures"), with an old preparation the process does not extract all of the alkaloid unless alcohol be added. The process may be modified in this way. When the chloroform washings (shaken with the fluid extract or concentrated tincture) cease to give a residue which reacts with Mayer's reagent in acid solution, add 10 Cc. of alcohol to the separator, and a fresh portion of chloroform and again shake. Evaporate about 1/2 Cc. of the chloroformic solution which has separated, on a watch glass, add two or three drops of diluted sulphuric acid, then a drop of Mayer's reagent. If a precipitate occurs the extraction must be continued until chloroform ceases to remove any alkaloid from the aqueous-alcoholic liquid.

Cinchona.—In order to secure constant results in ether-soluble alkaloids, the aqueous solution from which the final extraction with ether is made, must be fairly uniform in volume. Hydrochloric acid extracts more rapidly than sulphuric, and 25 Cc. of 2 per cent. hydrochloric acid is usually sufficient. If less than this is used, the mixed acids may be diluted to 25 Cc. If more is used they should be evaporated to 25 Cc., or some larger bulk of acid solution designated for the final shaking with ether. The temperature and time of standing in the final extraction are also important.

Coca.—Coca preparations are unreliable at best, and should be dropped; but if coca or preparations of coca are to be assayed, the first extraction should be with petroleum ether to eliminate the hydrolyzed alkaloids. When ether (ethyl oxide) is used, the results will depend entirely upon how much ether was employed, and the alkaloid extracted will always be a mixture. With petroleum ether, cocaine is the result, and concordant assays can be made. With ethyl ether, half or more of the alkaloids obtained may be eogenine.

Colchicum.—Colchicine, which is soluble in water, is easily changed to colchicine, which is almost insoluble in water, by heating the aqueous solution. This is the first difficulty in the assay, and if a high percentage of alkaloid is present there is considerable danger that a portion of it will be hydrolyzed and filtered out. This is particularly likely to occur in the assay of colchicum extract, which is rich in alkaloids.

To avoid this formation of the insoluble colchicine, it is necessary that the alkaloidal solution be kept neutral or acid, and that heat be avoided as much as possible, for hydrolysis will occur even in acid solution, with heat. And it is evident that it does occur in the heating of the aqueous solution in the U. S. P. assay, to some extent.

A second difficulty is that of obtaining a full yield of alkaloid which will be free from fat, not an easy matter when a single filter is depended upon to remove it. I prefer to add a fragment of paraffin to solidify the fat, when a perfectly clear filtrate, without oil streaks or globules, is obtained. I also prefer the Gordin-Prescott method of assay, which has received
preference in the Drug Bureau of the Department of Agriculture, by L. F. Kebler, Chief, after comparative tests. But colchicum assays offer a fruitful field for investigation.

*Conium.*—The official assay is tedious. Since conine has a markedly alkaline reaction, and is easily titrated, a volumetric assay would seem to be preferable. The alkaloid may be extracted from an alkaline (carbonate) solution by ether or petroleum ether, the ethereal solution evaporated by an air-blast over a measured quantity of deci-normal acid, and the latter titrated. Such a method is much quicker than the U. S. P., and gives concordant but lower results. Its accuracy remains to be shown.

*Gelsemium* and preparations should be assayed.

*Guarana.*—The process is quite satisfactory. It can also be used for Kola and preparations.

*Hydrastis.*—Too much of the drug is used. The alkaloids precipitated from 10 gm. of drug come down in masses which the ether is unable to dissolve, even when used in large excess. The alkaloids finally weighed should represent not more than 5 gm. of drug, and 2.5 gm. is better.

The assay processes for the fluidextract and tincture are almost free from berberine, because of precipitation with potassium iodide. It would seem better if the drug and its preparations were all assayed by the same general method.

Puckner's modification of the fluidextract assay (washing the insoluble portion on the filter instead of taking an aliquot portion of the filtrate) gives a little higher, and probably more accurate results, and takes twice as much time for the assay. Since comparative and not absolute results are the essential thing, it is a question whether the higher results are worth the additional time and labor.

Fluidextract of hydrastis has several times been found with crystals of hydrastine in the bottom of the bottle and the official strength appears to be about as high as the menstruum will hold of hydrastis.

*Ipecac.*—Too much drug is used. The alkaloidal residue from 10 gm. of drug or 10 Cc. of fluidextract is so highly colored that titration is very difficult. If the assay be based on 5 gm. of drug or 5 Cc. of fluidextract for final results, much less coloring matter is extracted and titration is easier. Even then the amount of alkaloid finally titrated is larger than in most of the U. S. P. assays.

It is impracticable to extract the alkaline aqueous fluid (obtained by rendering the acid washings alkaline) until it gives no test with Mayer's reagent. The ethereal washings should be tested after thorough shaking.

In filtering the acid-aqueous fluid obtained in the first step of the process from the fluidextract, a clarifying agent is helpful.

*Nux Vomica.*—This assay forms emulsions very easily which are best avoided by the use of stronger acid for extraction. I prefer to use a 10 per cent. sulphuric acid in the first shaking and a 5 per cent. acid in sub-
sequent shakings, when there is little danger of emulsifying. Any slight emulsion which may form at this stage is easily broken by heat.

It is not always practicable to extract the acid solution, after rendering alkaline, until it ceases to react with Mayer's reagent. The chloroformic solutions must be tested to ascertain when extraction is complete.

The necessity for using a nitric acid which contains a trace of nitrous acid for oxidizing the brucine, has several times been pointed out. The safer plan is to add a fragment of sodium nitrite, or to warm the strong acid with a few granules of sugar, as suggested by Dr. Lyons.

The directions to evaporate the fluidextract or tincture to dryness, then dissolve the residue in a mixture of ether, chloroform and ammonia, are impracticable. The residue may be softened with ammonia water, then rinsed into the chloroform (ether is unnecessary) with water, but the volume must be kept down to its lowest possible limits or a troublesome emulsion will be formed.

**Opium.**—During the last six or seven years I have made a considerable number of comparisons between the U. S. P. and Stevens' method of assay. The results have been so constantly in favor of the latter method that I have practically abandoned the U. S. P. method.

Stevens' method gives results about 0.1 per cent. higher than the official method, and the results are quite as uniform. It takes less than a quarter as much time, gives a very pure morphine, and is simple in operation. It calls for accurate measurement of the water used, and only a burette is suitable for measuring. It is altogether a more desirable method of assay.

**Physostigma.**—This drug gives troublesome emulsions which can scarcely be avoided when the weak acid directed by the Pharmacopoeia is used. A 10 per cent. acid avoids this, and hydrochloric acid extracts the alkaloids more rapidly than sulphuric. The 10 per cent. hydrochloric acid can be used in 5 Cc. portions, and when extraction is completed, the mixed acid solutions are best neutralized with solid sodium bicarbonate, cautiously added. In this way the total bulk of liquid is kept small, and the assay proceeds smoothly. The amount of tincture used for assay should be doubled.

**Pilocarpus.**—The assay process is quite satisfactory. The amount of fluidextract used for assay should be doubled, and the alkaloids from 10 Cc. obtained for the final titration.

**Veratrum.**—Should be assayed and its preparations standardized.

**The Chairman:** The paper is before you, and as we have a number of others along the same line I would suggest that if practicable, you confine your remarks to the distinct question pervading the paper, or to making any exceptions that you care to make, to the statements made, and then take up the general discussion of the subject of pharmaceutical assays after these several papers have been read. Are there any exceptions to be taken to the statements made by Mr. Scoville?
MR. A. H. CLARK: I would like to ask Mr. Scoville a question. He says he has found difficulty in old preparations of belladonna, scopola, hyoscyamus and stramonium, in extracting all of the alkaloid.

MR. SCOVILLE: Yes, not in the drug, so far as I know, but the extracts and tinctures.

MR. CLARK: We have an extract of stramonium in our school, which was originally assayed by Professor Puckner, and has been every year since by myself, it is now, I think, seven or eight years old, and is the same to-day as when it was made. We have no difficulty at all with it.

MR. SCOVILLE: I would like to ask if you have any trouble in the emulsion forming?

MR. CLARK: None at all, to speak of. I have never had any trouble with this particular preparation at least.

THE CHAIRMAN: Mr. Lyons has just come in, and we will get him to read his paper on "Assay Processes of the U. S. P."

Mr. Lyons here read his paper, as follows:

ASSAY PROCESSES OF THE U. S. PHARMACOPOEIA.

BY A. B. LYONS.

The assay processes of the U. S. P., VIII, were the outcome of a vast amount of pioneer work. It would be strange if they were not capable of great improvement. They have been severely criticised for their shortcomings and inconsistencies, and yet in the hands of experienced operators they have nearly all proved to be practical and capable of giving a fair indication of the quality of the drug or preparation assayed. At the same time there is room for improvement, and the next revision is likely to show a great advance in this department.

GENERAL CONSIDERATIONS.

1. In the present Pharmacopoeia there is provided for each drug and for each preparation assayed, with a few exceptions, a special assay process, every step of which is described in minute detail. This involves much needless repetition. For a number of the assays a single process may be employed which should be described in detail in the Appendix and not repeated under each drug. In a similar way a model process could be prescribed for the assay of a fluidextract and another for that of an extract. Only in the few cases where these model processes require modification would it be necessary to give in the body of the Pharmacopoeia a detailed process.

2. An obvious fault in our present assay processes is the absence of identification tests for the alkaloids separated in the assay. In most cases, indeed, it is a mixture of alkaloids that is obtained, but results will be unsatisfying if there is not some proof that the alkaloids found are such as should be present. One check on results is so easily applied that it should be part of the routine of every assay in which the alkaloid is determined.
by titration with volumetric acid. The weight of the alkaloid separated should invariably be noted and compared with the result of the titration. As a rule titration gives a figure notably less than the observed weight of the crude alkaloid—often ten or even twenty or twenty-five per cent. less. When the molecular weight of the alkaloid is very high, as in the case of aconitine, the presence of some other alkaloid will reveal itself by a titration result exceeding the weight of the crude alkaloid.

3. In our present assay processes the alkaloid is generally extracted from the drug or extract, the ethereal solution "shaken out" with acid, and the alkaloid again extracted in purer form by shaking out with an appropriate solvent after rendering the solution alkaline. Some loss of alkaloid in this triple extraction is inevitable. In the assays of the Swiss Pharmacopœia there is generally a single extraction of the alkaloid, which is then determined by direct titration with volumetric acid. Results are generally distinctly higher by this method, but it is possible that our method gives as true a valuation of the drug. The new committee will no doubt give the two methods a careful study and decide which on the whole gives the more trustworthy results.

4. In our present assay processes alcalimetrical titrations are in most cases prescribed for determination of the several alkaloids. Results of such titration are not always satisfactory. Query. Is there not some other way of making determinations of some of the alkaloids? A paper recently published by Dr. Heikel Gunnar has revived interest in the use of Mayer's reagent, once extensively used, but discarded of late years as lacking in exactness. Dr. Gunnar adds to the solution containing an alkaloid an excess of Mayer's reagent, and then determines the excess of mercury by titration with silver nitrate after addition of potassium cyanide. He claims a degree of exactness for his results that should make it available for the purposes of drug standardization. It may prove in the case of certain drugs to afford the most expeditious procedure. Even if it be not adopted as the official method of determining any alkaloid, it may at least serve to confirm the result of alcalimetrical titration where there is doubt regarding the identity of the alkaloid extracted. In case at least of colchicine it furnishes certainly the only titration method as yet known.

OPIUM ASSAY.

The lime assay has still warm advocates, and it commends itself by its rapidity and by the exceptional purity possible of the morphine which it extracts. However, the process involves the principle of the aliquot part, with an inevitable uncertainty about the aliquot, and hence will practically not find favor with the new committee.

Our present assay method is satisfactory, but may be improved in several particulars. The two filters on which the morphine is collected should be of exactly equal weight [or else the difference in weight, which
should not exceed ten milligrams, should be marked plainly on the outer (heavier) filter, and taken into account in the weighing of the morphine], and the morphine should be weighed after drying on the inner filter, with the outer used as counterpoise. It is not necessary to pass the ether through the filter. It should be decanted into a small beaker (to make sure that no morphine crystals go with it), and then rejected, using afterwards three portions at least of 15 Cc. each to complete the removal of narcotine, etc., each portion being decanted into the beaker before rejection. The solution containing the morphine crystals is to be brought upon the double filter in the usual manner, and when this has drained, the remaining crystals in the beaker and flask are to be transferred to the filter by aid of a saturated aqueous solution of morphine, with which the crystals are to be thoroughly washed. When drained, the filters containing the crystals are to be carefully removed from the funnel, pressed with caution between folds of filter-paper, and dried at a temperature not exceeding 60° C.

The crystals after weighing are to be transferred to a small beaker, in which they are to be treated with a concentrated lime solution, such as the liquor calcis saccharatus of the British Pharmacopoeia. This will dissolve the morphine almost instantly. The solution is to be filtered through the same double filter, which is to be washed with distilled water, of which no more should be used than necessary, the filters again dried and the insoluble residue weighed and deducted from the weight of the crude morphine.

An alternative method which seeks to obtain the morphine in a condition sufficiently pure for weighing is the following: After reducing the opium solution to a weight of 20 Gm., add 80 Cc. of alcohol, U. S. P., shake the flask well, and set aside until the precipitate settles. Filter the solution through a small filter, wash the precipitate on the filter with a mixture of alcohol 4 volumes, water 1 volume, until the filtrate runs through quite colorless, evaporate the alcoholic solution to a syrupy consistence, add distilled water 25 Cc., evaporate once more to a syrup, transfer to a small Erlenmeyer flask, and make up with distilled water to 20 Gm. From this point proceed as usual, with modifications given above. The morphine is so nearly pure that it is not necessary to treat it with a lime solution. If desired it may be dissolved in volumetric acid, and the morphine determined by residual titration with volumetric alkali.

CINCHONA ASSAY.

A capital improvement in this assay is the initial procedure adopted in the new Swiss Pharmacopoeia. The powdered bark is put into a flask with a prescribed quantity of diluted hydrochloric acid and heated on a steam bath during fifteen minutes. After cooling a given weight of ether-chloroform (2:1) is added followed by a solution of sodium hydroxide.
The mixture is then shaken vigorously and continuously during ten minutes, powdered tragacanth is added, the mixture shaken and left at rest five minutes, after which an aliquot portion of the ether-chloroform is poured off. The treatment with hydrochloric acid effects a very rapid and complete extraction of the alkaloid; herein consists the important improvement. Another improvement consists in the direct titration of the crude alkaloid with volumetric acid. The alkaloidal residue is treated three times with ether (5 Cc.) which is evaporated; it is then dissolved in absolute alcohol, haematoxylin indicator is added, and decinormal hydrochloric acid is run in from a burette until the color changes to red-brown. More water is then added and the titration continued until the color becomes citron yellow, each Cc. of decinormal acid corresponding with 30.4 milligrams of alkaloids. The whole procedure—determination of total alkaloids—consumes less than one hour, and duplicate assays are said to agree well.

For practical purposes, the U. S. P. plan of determining alkaloids gravimetrically is probably equally good, although the alkaloidal residue contains a not inconsiderable proportion of impurities.

Whether or not a double standard for cinchona bark (yellow) is desirable, we certainly gain more complete information regarding both the therapeutic and the commercial value of a bark by ascertaining in addition to the percentage of total alkaloids the proportion of "ether soluble" alkaloids present. The process of the U. S. P. VIII for determining this datum is faulty, in that the prescribed conditions do not insure complete separation of the "insoluble" alkaloids. The ethereal solution of the alkaloids is brought to a temperature below 20° C., and shaken continuously two minutes, then allowed to stand ten minutes at 15° C. The directions should be to reduce the temperature to 15° C., and shake continuously ten minutes, maintaining that temperature; otherwise the solution should be kept for a much longer time—at least 30 minutes—at 15° C., the preliminary shaking having been continued as much as three or four minutes.

Determination of quinine by any one of the several methods that have been proposed, or gravimetric determination of precipitated tartrates (indicating the proportion of combined quinine and cinchonidine), are procedures needlessly circumstantial and time-consuming, and therefore can hardly be recommended in the approximate valuation of cinchona and its preparations.

**Aconite Assay.**

There seems no good reason for employing in this assay a process differing in any essential particular from that prescribed for the mydriatic drugs. Pure ether is perhaps to be preferred to ether-chloroform as the final solvent in extracting the alkaloid. It is particularly important in this assay to make sure that the alkaloid determined consists really of aconitine.
It seems probable that in assays of the crude drug, if the drug is fresh and in good condition, the alkaloid obtained by the official assay process does usually consist mainly of aconitine. Old samples of drug, particularly if they have been exposed to dampness, and preparations of the drug that have been extracted by aid of heat, yield alkaloid much of which is not aconitine. Hence it is necessary always to weigh the alkaloidal residue as a check on the titration, and advisable also to resort to Squibb's test. A tincture (1:700) of an aconite which yields 0.5 per cent. “aconitine” by the U. S. P. assay process should produce pronounced tingling of the tongue and lips when tested by Dr. Squibb’s method.

The new French Codex prescribes a method for determining aconitine quite different from that of any other pharmacopoeia. An aqueous solution of the alkaloid in form of a nitrate is precipitated with silico-tungstic acid. The precipitate is collected on a filter, washed, dried at 100° C., ignited and weighed. The weight of the residue of silica is multiplied by the factor 0.793 to give the weight of the aconite. This plan should be studied by the new committee, and may possibly prove to be the best solution of the problem of a reliable aconite assay.

**COLCHICUM ASSAY.**

The method adopted by the U. S. P. for purifying crude colchicum for gravimetric determinations is far from satisfactory. The impurities on the one hand are not completely removed, while alkaloid is unquestionably lost. One of the most satisfactory methods for removing impurities consists in adding to the alkaloid some hard paraffin and treating with water to dissolve out colchicine. Another plan is to treat the aqueous solution from which colchicine is to be extracted with lead subacetate, filter, treat an aliquot portion of the filtrate with sodium phosphate in powder to remove excess of lead, filter again, and extract the colchicine with chloroform from an aliquot portion of the last filtrate. On the whole this plan seems as satisfactory as any that has been proposed.

Purification by solution in chloroform, addition of ether and precipitation with petroleum ether, is recommended by some. I have had no experience with it, but suspect that results obtained are too low.

Personally I have always maintained that colchicine could be most quickly and satisfactorily determined by the use of Mayer’s reagent, even when used by the old Jacobson method. Recently Dr. Gunnar Heikel has published a method by which quite exact results can be reached in titrations with Mayer’s reagent, and his method applied to colchicine determinations seems to leave nothing to be desired either in rapidity of execution or in practical accuracy of results.

Since this paper is intended only to introduce a discussion on assay methods of the Pharmacopoeia, it is better not to attempt to render it complete, but rather to direct attention to some of the more important
ASSAY OF OPIUM, NUX VOMICA, AND CINCHONA.

ASSAY OF OPIUM, NUX VOMICA, AND CINCHONA, BY THE PROCESSES OF SOME OF THE NEWER PHARMACOPEIAS.

BY A. R. L. DOHME AND H. ENGELHARDT.

Since the publication of the U. S. P. in 1905, thirteen pharmacopoeias of other countries have appeared. In the work about to be described, opium, nux vomica and cinchona were examined by the methods of eleven of these pharmacopoeias, two of them, i.e., the Russian and the Servian, having been omitted. The methods of these eleven books were compared with those of the U. S. P. and the two older pharmacopoeias, i.e., the German and the English pharmacopoeias. The methods are given in detail as follows:

OPIMUM.

1. U. S. P.

2. German Pharmacopoeia.

Six Gm. of the powdered opium are tritirated with 6 Gm. of water, the mixture rinsed with water into a dry tared flask, and more water is added until the weight of the mixture is 54 Gm. After allowing the flask to stand for one hour, with frequent shaking, the contents are pressed through a piece of dry muslin and 42 Gm. filtered through a dry folded filter of 10 Cm. diameter into a dry flask. To this filtrate 2 Gm. of sodium salicylate solution (1 to 2) are added, and the mixture shaken vigorously. After settling, 36 Gm. of the clear liquid are filtered through a dry filter of 10 Cm. diameter into a flask and mixed by rotating with 10 Gm. of ether and 5 Gm. of normal ammonia solution. The flask is then closed, shaken well for ten minutes and allowed to stand for 24 hours. Then first the ethereal layer is poured on a plain filter of 8 Cm. diameter, and to the aqueous liquid remaining in the flask 10 Gm. more of ether are added, the mixture rotated for a few minutes, and the ether poured on the filter again. After the ethereal liquid has been filtered, the aqueous solution is transferred to the filter and filter and flask washed three times with 5 Cc. of water saturated with ether. The morphine crystals on the filter are dissolved in 25 Cc. of tenth-normal hydrochloric acid and the solution poured into the flask in which the morphine was allowed to crystallize. The contents of the flask are then transferred to a graduated flask of 100 Cc. contents and
filter and flask washed with sufficient water to obtain 100 Cc. of solution. Of this solution 50 Cc. are transferred to a bottle of flint glass of about 200 Cc. contents, then 50 Cc. of water are added and sufficient ether to produce a layer of the latter about 1 Cm. thick. After the addition of five drops of iodeosin solution, tenth-normal caustic potash is added, shaking well after each addition, until the aqueous layer has assumed a pinkish color. For producing this color not more than 5.4 Cc. and not less than 4.1 Cc. of caustic alkali should be required. The aqueous liquid not used for titration should be used for the identification of morphine.

3. Danish Pharmacopoeia.

6 Gm. of dry powdered opium are triturated in a mortar with a small quantity of water, and transferred to a tared flask with sufficient water to make the total weight of the mixture 66 Gm. The flask is allowed to stand over night with occasional stirring, the mixture then filtered, and to 50 Gm. of the filtrate 2 Gm. of normal ammonia water are added, and after rotating, the mixture is filtered at once through a filter of 10 Cm. diameter. To 44.2 Gm. of the filtrate, equal to 4 Gm. of the opium, 10 Gm. of ether are added, the mixture mixed well by rotating and then 4 Gm. of normal ammonia was added. The flask is stoppered well and after shaking allowed to stand over night. A very complicated method of filtering the ether by the aid of a syphon is then given, and both the ether and the aqueous liquid containing the morphine are collected on two different filters. After the morphine is collected on the filter, it is washed with 5 Cc. of water saturated with ether and dried at 100° C. The morphine is then dissolved in 25 Cc. of tenth-normal hydrochloric acid and titrated in the usual way with iodeosin solution as indicator.

4. Swiss Pharmacopoeia.

6 Gm. of opium are triturated with 6 Cc. of water to a uniform paste and the mixture rinsed with water into a tared flask until 54 Gm. of mixture are obtained. The mixture is then allowed to stand for one-half hour with frequent shaking, when 38 Gm. are filtered through a dry folded filter of 10 Cm. diameter, mixed by rotation with 2 Gm. of normal ammonia solution, and filtered at once through a dry folded filter of 10 Cm. diameter. 36 Gm. of the filtrate are mixed in a flask with 10 Cc. of ether and 4 Gm. of normal ammonia solution. The bottle is then stoppered and shaken well for 10 minutes. To remove any emulsions produced by the shaking, 10 Cc. of ether are added and the mixture allowed to stand for one-half hour. After this period the ether solution is filtered through a filter of 8 Cm. diameter, and 10 Cc. more of ether are added, which is filtered also. Then the aqueous liquid is poured on the filter, and flask and filter washed twice with 5 Cc. of water saturated with ether. The flask and filter are dried at 100° C.
The crystals on the filter are then transferred as much as possible to
the flask and any morphine remaining on the filter dissolved in 25 Cc. of
tenth-normal hydrochloric acid, which is also added to the flask. The
solution in the flask is then transferred to a graduated flask of 100 Cc.
contents, and the filter washed with water until the solution measures 100
Cc. 50 Cc. are then titrated in the usual way with iodeosin. Not more
than 5.5 Cc. of tenth-normal caustic alkali and not less than 4 Cc. should
be necessary for producing a pink color in the aqueous liquid. 1 Cc. $^\text{N}_\circ$
acid is equal to 0.0285 Gm. anhydrous morphine.

5. Hungarian Pharmacopæia.

Opium dried at 60° C. should contain 10 per cent. of morphine. This
is determined in the following way: The opium is first freed from the
poppy leaves and the seeds of the various species of rumex with which the
gum opium is usually covered and dried at 60° C. 6 Gm. of the dried
powdered opium are then transferred to a tared Erlenmeyer flask, with
sufficient water to make the mixture weigh 54 Gm., and the mixture is
shaken well for a quarter of an hour. 42 Gm. of the aqueous liquid are
filtered through a filter of 8 Cm. diameter into a cylinder mixed, by gentle
rotation, with 2 Cc. of normal ammonia water, and then filtered at once.
36 Gm. of the filtrate are transferred to an Erlenmeyer flask of about 100
Cc. contents, 10 Gm. of pure acetic ether are added, the liquids mixed
well, and then 4 Gm. of normal ammonia water are added. The mixture
is shaken well for ten minutes, and after the addition of 10 Gm. of acetic
ether allowed to stand for ten minutes longer. The morphine is then col-
lected on a filter, washed with water saturated with acetic ether in the
usual way, and the morphine dried at 100° C. to a constant weight.

Six Gm. of the powdered opium are transferred to a tared flask and
water is added until 54 Gm. of the mixture are obtained. The mixture is
shaken for fifteen minutes and then filtered through a filter of 10 Cm-
diameter. 38 Gm. of the filtrate are mixed with 2 Gm. of normal ammo-
nia water by rotating, and this mixture filtered at once. To 36 Gm. of the
filtrate 10 Cc. of acetic ether and 4 Gm. of normal ammonia water are
added, and the mixture shaken for ten minutes. Then 10 Cc. more of
acetic ether are added and mixed with the liquid. The liquid is then
filtered. First the acetic ether is poured on the filter, and after this has
passed through, 10 Cc. more of acetic ether are added, mixed with the
liquid, and filtered again. Then the aqueous liquid is poured on the filter
and the morphine, after perfect draining, washed with 5 Cc. of water satu-
rated with acetic ether. The residue on the filter is then dissolved in 25
Cc. of $^\text{N}_10$ normal hydrochloric acid, the solution filtered into a glass-
stoppered flask and the filtrate washed with water until about 100 Cc. of
total liquid are obtained. The acid liquid is then titrated in the usual way with iodeosin as indicator.

7. Austrian Pharmacopœia.

6 Gm. of powdered opium, previously dried at 100° C., are triturated in a mortar with 10 Gm. of water and transferred to a tared flask with sufficient water to obtain 60 Gm. of mixture. The flask is then shaken for 1/4 hour and the mixture filtered through a filter of 10 Cm. diameter. 43 Gm. of the filtrate are mixed by rotating with 2 Gm. of ammonia water and filtered at once through a filter of the same size. To 40 Gm. of the filtrate, 10 Gm. of acetic ether and 4 Gm. of normal ammonia water are added, and the mixture shaken for ten minutes. Then 10 Cc. more of acetic ether are added and the mixture filtered in the usual way through a tared filter and the flask and filter washed with about 5 Cc. of water saturated with acetic ether. The morphine is then dried at 100° C., and weighed.

8. Belgian Pharmacopœia.

6 Gm. of powdered opium, previously dried, are triturated in a mortar with 6 Gm. of water and then transferred to a tared flask with sufficient water to make the total weight of the mixture 54 Gm. The flask is then allowed to stand for one hour, and 42 Gm. of the liquid are filtered through a folded filter of 10 Cm. diameter. To the filtrate 2 Gm. of normal ammonia water are added, mixed well by rotation, and the liquid filtered at once through a folded filter of 10 Cm. diameter. 36 Gm. of the filtrate are mixed in a weighed Erlenmeyer flask with 10 Cc. of acetic ether and 4 Gm. of normal ammonia solution are added. After shaking continuously for 10 minutes, 10 Cc. more of acetic ether are added to break up the emulsion. The liquid is then filtered, pouring off the acetic ether first. After this has passed through the filter, 10 Cc. more of acetic ether are added, mixed by rotation, and decanted again. Then the aqueous liquid is added to the filter and the flask washed twice with 5 Gm. of water saturated with acetic ether, which is also added to the filter. After the flask and filter have drained well they are heated to 100° C. The crystals on the filter are then transferred to the flask, and the heating continued until a constant weight is obtained.

Triturate together 14 Gm. of dry powdered opium, 6 Gm. calcium hydroxide, and 40 Cc. of water in a mortar until a uniform mixture results; add 100 Cc. of water and stir occasionally during half an hour. Filter the mixture through a plaited filter, about 10 Cm. in diameter, into a wide-mouthed bottle, having a capacity of about 300 Cc., and marked at exactly 104 Cc., until the filtrate reaches this mark. To the filtered liquid (representing 10 Gm. of opium) add 10 Cc. of alcohol (90 per cent.)
and 50 Cc. of ether; shake the mixture; add 4 Gm. of ammonium chloride, shake well and frequently during half an hour; set aside for twelve hours for the morphine to separate. Countercalance two small filters; place one within the other in a small funnel in such way that the triple fold of the inner filter is superposed upon the single fold of the outer filter; wet them with ether; remove the ethereal layer of the liquid in the bottle as completely as possible by means of a small pipette, transferring the liquid to the filter, rinse the bottle with 20 Cc. of ether, again transferring the ethereal layer by means of the pipette, to the filter; wash the filter with a total of 10 Cc. of ether, added slowly and in portions. Let the filter dry in the air, and pour upon it the contents of the bottle in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the bottle with morphonated water until the whole has been removed. Wash the crystals with morphonated water until the washings are free from color; allow the filter to drain, and dry it, first by pressing between sheets of bibulous paper, afterwards at a temperature between 131° and 140° F. (55° and 60° C.) finally at 230° F. (110° C.) for two hours. Weigh the crystals in the inner filter, counterbalancing by the outer filter. Take 0.5 Gm. of the crystals and titrate with decinormal volumetric solution of sulphuric acid until the liquid, after boiling, slightly reddens blue litmus paper. 1 Cc. of this volumetric solution represents 0.0283 Gm. of pure anhydrous morphine. The weight of pure anhydrous morphine indicated by the titration, plus 0.104 Gm. (representing the average loss of morphine during the process) should amount in total to 1 Gm., that is to say, to a total of not less than 0.95 Gm., and not more than 1.05 Gm. corresponding to about 10 per cent. of anhydrous morphine in the dry powdered opium.

10. Dutch Pharmacopœia.

3.3 Gm. of the opium are triturated with about an equal weight of water, then 10 Cc. of water are added. The mixture is transferred into a weighed bottle. Ten Cc. of a freshly prepared mixture of calcium hydrate and water (1 = 20) are added and then sufficient water to make the contents weigh 35 Gm. The mixture is shaken repeatedly during three hours and then filtered through a folded filter of 4 Cm. diameter. Twenty Gm. of the filtrate, equal to 2 Gm. of the powdered opium, are mixed with 10 Cc. of ether, and 0.200 Gm. of ammonium chloride, shaken continuously during one-quarter of an hour, and then allowed to stand for 24 hours. Five Cc. of ether are then added and the ethereal liquid is filtered through a dry filter. To the aqueous liquid 5 Cc. more of ether are added, which are filtered also. Then the aqueous liquid is collected on the filter and the flask and filter washed with water until one drop of the filtrate does not color phenolphthalein solution. About 15 Cc. of water will be neces-
sary. The morphine on the filter and the morphine which remained in
the flask are then dissolved in 20 Cc. of tenth-normal sulphuric acid, the
acid solution filtered into another flask, the filter and flask washed well
with water until the latter no longer shows an acid reaction, and the excess
of acid, after the addition of five drops of hematoxylin solution, titrated
back.

Introduce 10 Gm. of powdered opium with 4.5 Gm. of slaked lime into
a glass bottle; add 100 Cc. of water, cork the bottle, and extract by shaking
it strongly in the cold for two hours. Transfer the contents of the bottle
to a piece of cloth placed over a filter-paper, and filter the liquid obtained
by squeezing. Take 50 Cc. of the filtrate, together with 5 Cc. of alcohol,
in a bottle, cork it tightly, shake and filter; mix 44 Cc. of this second fil-
trate with 20 Cc. of ether and 2.5 Gm. of ammonium chloride, in a suitable
glass vessel which is to be stoppered; shake it strongly for half an hour
and after setting aside for 24 hours, collect the precipitate produced upon
a filter-paper previously dried and weighed, wash it with 10 Cc. of water
and dry at a temperature not exceeding 60° C.; after cooling, wash the
precipitate on the filter-paper again with 10 Cc. of pure ether, and after
drying by heating first gently, and then at 96°–100° C. for about four hours,
put into a dessicator, allow to cool, then the crystals should weigh 0.4–
0.44 Gm.

Triturate in a mortar 15 Gm. of opium dried at 95° C. and mix with 8
Gm. of recently slaked lime. Place the mixture in a tared dish with 150
Gm. of distilled water and heat to a temperature of 50° to 60° C. for two
hours, stirring from time to time and replacing the liquid which evapo-
rates. Filter after cooling and collect 106 Cc. of the filtrate which corre-
spond to 10 Gm. of opium. Place this in a flask and add 25 Cc. of ether
and 3 Gm. of pure ammonium chloride. Shake carefully by rotating to
avoid emulsions, allow to stand in a cool place for three hours or more
and then decant the liquid. Add two more portions of ether, shaking
and decanting each time. Having united the "ethereal" liquids* allow
them to stand for twelve hours, at the end of which collect the precipitate
formed on a small filter. Wash with 10 Cc. of distilled water and dry at
a temperature not higher than 95° C. The morphine is afterward treated
with chloroform to separate the narcotine and is again dried and weighed.

One Gm. of morphine should be obtained, but generally 0.92 to 0.94
Gm. are actually obtained, since losses of 0.06 to 0.08 Gm. can occur, due
to imperfect precipitation and to washing.

* "Liquidos etereos" in the original. This should evidently be "aqueous liquids," since morphine is insoluble in ether.
13. French Codex.

7½ Gm. of powdered opium, previously dried at 60° C., are mixed with 3 Gm. of finely powdered slaked lime, and to the mixture 25 Cc. of distilled water are added and stirred well until a uniform mixture is obtained. The mixture is then transferred to a glass-stoppered bottle of 125 Cc. capacity with 50 Cc. of water and mixed well by rotation. After two hours, with frequent rotation, the mixture is thrown on a filter of 14 Cm. diameter and 52 Cc. of the filtrate transferred to an Erlenmeyer of 125 Cc. capacity. Then 15 Cc. of ether are added, and, after mixing well 1 Gm. of pure ammonium chloride, and the mixture stirred well with a glass rod until crystals of morphine appear. The flask is then stoppered and allowed to stand for 24 hours after removing the glass rod. The ether is then filtered through counterpoised plain filters and 15 Cc. more of ether are added to the flask, the contents shaken, the ether filtered, and then the aqueous liquid. Then 8 Cc. of water saturated with morphine and ether are added to the crystals of the flask and the contents thrown on the filter. This latter filtrate, which is collected separately, is used for transferring the crystals in the flask as much as possible onto the filter, and the flask and funnel are washed with water saturated with morphine and ether, until the wash water does not produce any cloudiness with silver nitrate solution. The filters are then dried at 100° C. for about two hours, and after cooling, the crystals are washed three times with 8 Cc. of petroleum ether and dried again. After they are perfectly dry they are allowed to cool and the morphine is weighed. At least 0.5 Gm. and at most 0.55 Gm. of morphine should be obtained.

10 Gm. of powdered opium previously dried at 60° C., are allowed to macerate for one hour, with frequent shaking, with 90 to 100 Cc. of a 20 per cent. solution of sodium chloride. The liquid is then decanted, allowing as much as possible of the opium to remain in the bottle. This is then macerated again with 60 Cc. of sodium chloride solution of the same strength and this process is repeated until the filtrate no longer gives a reaction for the morphine with Froehde's reagent. The combined solutions are then evaporated to dryness on a water-bath, the dry residue is extracted with boiling absolute alcohol, and the extraction repeated until no more morphine is taken up by the latter. The alcohol is distilled off and the residue taken up in 14 Cc. of water, with the aid of heat, and after cooling, sufficient ammonia water is added until the mixture smells distinctly of ammonia. The bottle is then stoppered and allowed to stand for 24 hours in a cool place, after which the precipitate is filtered on a tared filter and washed with water saturated with morphine until the filtrate becomes colorless. Filter and precipitate are then dried at 100° C. and the dry residue on the filter washed with chloroform or benzene,
until one drop of the filtrate evaporated and the residue taken up in hydrochloric acid gives no turbidity on the addition of sodium hydroxide solution. The residue and filter are dried at 100° C., and the former should weigh not less than 1 Gm.

**Nux Vomica.**

1 U. S. P.

2. German Pharmacopoeia.

15 Gm. of the powdered nux vomica, previously dried at 100° C., are shaken in a bottle with 100 Gm. of ether and 50 Gm. of chloroform, and then 10 Cc. of a mixture of two parts of caustic soda solution (15 per cent.) and one part of water are added and the mixture allowed to stand with frequent shaking for three hours. 15 Cc. or sufficient water are added until the powdered nux vomica after violent shaking balls together. After allowing to stand, 100 Gm. of the clear ethereal liquid are filtered through a dry well-covered filter and about 1/2 of the ethereal liquid is evaporated. The remaining chloroform-ether solution is then transferred to a separator, the flask rinsed out three times with 5 Cc. each of a mixture of three parts of ether and one part of chloroform, and the combined ethereal liquids shaken well with 10 Cc. of tenth-normal hydrochloric acid. After perfect clearing, if necessary by the addition of so much ether that the ether-chloroform solution floats on the acid liquid, the latter is filtered through a small filter previously wetted with water into a 100-Cc. graduated flask. The ethereal solution is then shaken three times with 10 Cc. each of water, the aqueous solutions filtered through the same filter and the filter washed with sufficient water to make the total amount of liquid measure 100 Cc. Of this solution 50 Cc. are measured off and titrated in the usual way with iodeosin solution. Not more than 15.6 Cc. of \(\frac{1}{10} \) normal caustic potash should be required to produce a pink color in the aqueous layer.

6 Gm. of powdered nux vomica are shaken for \(\frac{1}{2}\) hour with 40 Gm. of chloroform and 80 Gm. of ether. Then 5 Cc. of ammonia water are added and the mixture allowed to stand 24 hours with frequent shaking. The ethereal liquid is filtered into a tared flask of 300 Cc. contents and the filtrate weighed. The menstruum is distilled off, the residue dissolved in 5 Cc. of absolute alcohol, and after solution has taken place, 10 Cc. of water, three drops of hematoxylin solution and 30 Cc. of ether are added and the mixture titrated with tenth-normal hydrochloric acid, until the aqueous liquid has assumed a red-brown coloration. Then the flask is shaken well and 30 Cc. more of water are added and the titration with acid continued until the aqueous liquid has assumed a lemon-yellow color after violent shaking.
For each 10 Gm. of the ethereal solution not less than .34 Cc. of tenth-normal hydrochloric acid should be used for neutralization.

4. Dutch Pharmacopoeia.

It is directed that the nux vomica should first be exhausted with petroleum ether before the assay is made. 10 Gm. of the nux vomica, freed from fat, are mixed with 100 Cc. of chloroform and 10 Cc. of ammonia water and the mixture is shaken well for three hours. The chloroform solution is then filtered and the chloroform distilled off from 70 Cc. of the filtrate. The residue is dissolved in 3 Cc. of alcohol and mixed with 10 Cc. of tenth-normal hydrochloric acid, the acid solution is filtered through a wetted filter and the filter washed with water until the filtrate no longer gives a reaction for alkaloids. After the addition of 2 drops of hematoxylin solution the excess of acid is titrated back with tenth-normal caustic potash solution.

5. Swedish Pharmacopoeia.

7½ Gm. of the powdered drug are transferred to a bottle of 200 to 300 Cc. capacity and mixed with 150 Cc. of a mixture of 4 volumes of ether and one volume of chloroform, and 10 Cc. of caustic potash, and shaken occasionally during one hour. Then 25 Cc. of water are added, and the mixture shaken until the powder balls together. After clearing, the ethereal liquid is filtered and 100 Cc. distilled until about 1 Cc. remains. This residue is mixed with 10 Cc. of \( \frac{1}{10} \) normal hydrochloric acid and 25 Cc. of water and the balance of the chloroform evaporated. The acid liquid is then filtered into a bottle of 100 Cc. contents, the filter washed well, and the excess of acid titrated in the usual way with iodeosin as indicator.

No assay process is given.

Mix 15 Gm. of nux vomica in medium powder dried at 100° C., with 139 Cc. of ether and 33.5 Cc. of chloroform, and shake strongly, add 10 Cc. of a mixture of 2 parts of sodium hydroxide solution and one part of water, and allow the mixture to stand, with frequent shaking, for three hours. Then add to the mixture 15 Cc. or more of water, and let the powder collect together by shaking strongly, and set aside for one hour. Filter 115 Cc. of the clear chloroform-ether solution into a small glass flask, through a dry filter paper placed in a well-covered funnel; distill the filtrate till it becomes about one-half of the original bulk; transfer the remaining chloroform-ether solution to a separating funnel, and wash the small flask thrice, each time with 5 Cc. of a mixture of 6 parts of ether and 1 part of chloroform; add the washings to the main solution in the separating funnel and shake the mixed liquid strongly with 10 Cc. of deci-
normal hydrochloric acid solution. After complete separation of the ether-chloroform solution, adding, if necessary, a suitable quantity of ether, filter the lower clear acid layer into a colorless glass flask of 100 Cc. capacity, through a small paper filter which is previously moistened with water; shake the chloroform-ether solution successively for three times, each with 10 Cc. of water, the aqueous layer being separated and filtered each time through the same filter-paper, which is finally washed with water; mix all the filtrates and dilute the mixture to 100 Cc. by adding water. Transfer 50 Cc. of the diluted solution to a colorless glass flask of about 200 Cc. capacity; add about 50 Cc. of water and some ether, until the latter forms in the bottle a layer of about 1 Cm. in thickness, and after adding five drops of iodeosin solution, titrate the excess of the acid in the resulting solution by pouring in drop by drop, centinormal potassium hydroxide solution, with strong shaking; then not more than 15.6 Cc. of the latter solution should be required, before the lower aqueous layer acquires a light red coloration.

8. Spanish Pharmacopoeia.

No assay process is given.

Twelve Gm. of the powdered nux vomica, previously dried at 100° C., are mixed in a glass-stoppered bottle with 20 Cc. of chloroform and 100 Cc. of ether. Stopper the flask well and shake for five minutes. Then add 5 Cc. of a mixture of equal volumes of official ammonia water (20 per cent.) and distilled water. Shake frequently during three hours. Allow to clear, and filter 80 Cc. of the ether-chloroform liquid, equal to 8 Gm. of the drug, through a funnel covered with a glass plate. Transfer the ethereal liquid to a separator, and shake out with 25, 15 and 10 Cc. of a mixture of 2 Cc. of hydrochloric acid (33.6 per cent.) and 48 Cc. of water. Combine the acid solutions in another separator, add to it 50 Cc. of a mixture of ether and chloroform (no proportions given; probably a mixture similar to that used for extracting the drug. E.) and then an excess of dilute ammonia water, about 8 Cc., and shake well. Draw off the ammoniacal liquid into a second separator and shake out again with 50 Cc. of ether-chloroform mixture. Draw off the aqueous liquid and combine the ether-chloroform mixtures. Shake out with 2 Cc. of distilled water which is rejected; evaporate the chloroform-ether mixture in two portions in a flask of 90 Cc. capacity, dry the residue at 100° C. and weigh. By multiplying the weight by 12½ the percentage of alkaloids is obtained.

10. Italian Pharmacopoeia.

Should contain 2½ per cent. of total alkaloids and is assayed in the following way: The powdered nut is first extracted with petroleum ether to
remove the fat. Six Gm. of the powdered nux vomica are transferred to a bottle of about 300 Cc. capacity and 100 Gm. of ether and 50 Gm. of chloroform are added, the mixture shaken well, and after the addition of 10 Cc. of ammonia water, shaken again well for five minutes. (No assay process for the drug is given. It is directed that the assay should be carried out by the process given for the extract. While five minutes' shaking is sufficient to liberate the alkaloids from the extract, this time is entirely insufficient to set the alkaloids free from the drug. The time should be extended to at least one-half hour. E.). The mixture is then allowed to clear, and the ethereal liquid is filtered through a small filter. From 100 Cc. of the filtrate the ether-chloroform is distilled off, and the residue taken up in 10 Cc. of tenth-normal sulphuric acid, applying gentle heat. The acid liquid is then filtered into a separator and the flask and filter washed three times with 3 Cc. of acid of the same strength, and finally twice with 2½ Cc. of water. To the acid liquid ¾ of the above distillate of ether-chloroform and 5 Cc. of ammonia water are added, and the mixture shaken from 5 to 10 minutes and allowed to stand for one hour. The aqueous part is then separated and the ether-chloroform liquid shaken twice with 2½ Cc. of water, which is rejected. The ethereal liquid is then filtered into a small tared flask, the separator washed with the remaining part of the ether-chloroform distillate, which is also filtered into the flask, the liquid evaporated, and the residue dried to constant weight.

11. Hungarian Pharmacopœia.

Nux Vomica should contain 2½ per cent. of total alkaloids, which are determined in the following way: To 5 Gm. of the powdered drug 25 Gm. of chloroform and 50 Gm. of ether are added and after allowing to macerate for one-half hour 4 Cc. of ammonia water are added. The mixture is shaken well and continuously during one-quarter of an hour. After allowing to stand for one hour the ether-chloroform mixture is filtered and 60 Gm., equal to 4 Gm. of the drug, are transferred to an Erlenmeyer flask of 200 Cc. capacity.

The solution is then evaporated, the residue treated twice with 5 Cc. of ether, which is evaporated each time and then 30 Cc. of water saturated with ether are added and 10 Cc. of tenth-normal hydrochloric acid. After solution has taken place, the excess of acid is titrated in the usual way with iodesin as indicator.

12. Danish Pharmacopœia.

15 Gm. of nux vomica, previously dried at 100° C., are mixed with 100 Gm. of ether and 50 Gm. of chloroform. The mixture is shaken well, 10 Cc. of sodium hydroxide solution are added, and shaken occasionally during three hours. Then 15 Cc. of water are added, and the mixture shaken well, to make the drug ball together. 100 Gm. of the ether-
chloroform solution are then filtered into an Erlenmeyer flask through a filter covered with a glass-plate, and one-half of the ether-chloroform solution is distilled. The remaining mixture is then transferred to a separatory funnel and the flask washed three times with 5 Cc. of a mixture of three parts of ether and one part of chloroform, which is also added to the separator. Then 10 Cc. of tenth-normal hydrochloric acid are added and the mixture shaken well. After clearing, if necessary, by the addition of some ether, the acid solution is filtered through a small filter into a 200 Cc. flask, and the ether-chloroform solution shaken out three times with 10 Cc. of water which is also added to the acid solution. The titration of the alkaloids is then carried out in the usual way, using iodesin as indicator.

6 Gm. of powdered nux vomica are mixed with 60 Gm. of a mixture of three parts of ether and one part of chloroform. After allowing to stand for one-half hour, 5 Cc. of ammonia water are added, the mixture is shaken well and then mixed with 10 Cc. of water and shaken well again. 50 Gm. of the clear ether-chloroform solution are filtered and then shaken out with 20-15-5 Cc. of dilute hydrochloric acid (0.5 to 100) and the combined acid solutions made alkaline with ammonia water and shaken out twice with 60 Gm. of ether-chloroform solution of the above composition. The ether-chloroform mixture is then distilled off, and the residue treated twice with a few Cc. of ether, which is evaporated also. The residue is then dried at 100° C. to constant weight.

15 Gm. of the powdered nux vomica are intimately mixed with sand and then exhausted with 70 per cent. alcohol. The alcoholic solution is evaporated until 10 Gm. of residue are obtained. The residue is acidulated with acetic acid and then extracted with ether. After the ether has separated, the aqueous liquid is mixed with 50 Gm. of ether and 25 Gm. of chloroform and shaken well. Then 5 Gm. of ammonia water are added, and the mixture shaken for a few minutes and allowed to stand for one hour. The supernatant liquid is then filtered, and 50 Gm. of the filtrate evaporated in a tared flask. The menstruum is then distilled off, to the residue 10 Gm. of ether are added, which is evaporated again, and the residue dried at 100° C. to constant weight.

Cinchona.

1. U. S. P.

2. Austrian Pharmacopœia.

6 Gm. of powdered cinchona, previously dried at 100° C., are mixed with 60 Gm. of a mixture of three parts of ether and one part of chloro-
form, and after the addition of 3 Gm. of ammonia water and 10 Gm. of water, shaken frequently during twelve hours. Then gradually water is added (5 Gm. at the most) and 1 Gm. of gum tragacanth, the mixture shaken well, and allowed to stand for one hour. Fifty Gm. of the clear ethereal liquid are transferred to a separatory funnel and shaken out several times with a weak hydrochloric solution.

The combined acid solutions are then made alkaline with sodium hydroxide and shaken out with 20-10-5 Cc. of chloroform. Chloroform solution is collected in a tared flask, the chloroform distilled off, the residue dried at 100° C. and weighed.

3. German Pharmacopœia.

Twelve Gm. of the powdered cinchona, previously dried at 100° C., are mixed with 90 Gm. of ether and 30 Gm. of chloroform, and to the mixture 10 Cc. of caustic soda solution (15 per cent.) are added. With frequent shaking the mixture is allowed to stand for three hours. Then 10 Cc. or sufficient water is added and the mixture shaken until the powdered cinchona agglutinates, when it is allowed to stand until the chloroform-ether solution is perfectly clear. Then 100 Gm. of the clear ethereal solution are filtered through a well-covered filter into a flask, and about one-half of the ether-chloroform evaporated off. The remaining ether-chloroform solution is then transferred to a separator, the flask rinsed three times with 5 Cc. each of three parts of ether and one part of chloroform, and the combined liquids shaken well with 25 Cc. of tenth-normal hydrochloric acid. After perfect clearing, if necessary after the addition of sufficient ether to make the chloroform-ether solution float on the acid liquid, the latter is filtered into a 100-Cc. graduated flask through a small filter previously wetted with water. The ethereal liquid is then shaken out three times with 10 Cc. each of water. These aqueous extractions are filtered through the same filter, and the filter is washed with water until 100 Cc. of filtrate is obtained. Of this solution 50 Cc. are transferred to a bottle of 150 Cc. capacity mixed with a freshly prepared solution of a small piece of hematoxylin in 1 Cc. of alcohol and sufficient tenth-normal caustic potash is then added until the mixture has assumed a yellowish color, which turns to bluish violet on violent shaking. Not more than 4.3 Cc. of caustic alkali should be used for this purpose.

Mix 12 Gm. of the bark in fine powder, dried at 100° C., with 125 Cc. of ether and 25 Cc. of chloroform, and shake strongly; after adding to the mixture 10 Cc. of sodium hydroxide solution and setting aside for 3 hours with occasional strong shaking, let the powder collect together by adding 10 Cm., or still greater quantity of water and thoroughly shaking, and set aside for an hour; filter 125 Cm. of the clear chloroform-ether solution
into a small glass flask, by means of a well-covered funnel which is furnished with a dry filter-paper, and distill the filtrate till it becomes about half its original volume; put the remaining chloroform-ether solution into a separating-funnel, and wash the small flask 3 times, each with 5 Cc. of the mixture of 6 Cc. of ether and 1 Cc. of chloroform, and add the washing to the solution in the separating-funnel; shake the mixture strongly with 25 Cc. of decinormal hydrochloric acid solution, if necessary, with the addition of a suitable quantity of ether; when the layer of the chloroform-ether solution separates, take the lower, clear, acid layer, and filter it into a colorless glass flask of 100 Cc. in capacity, by means of a small filter-paper which is previously moistened with water; add 10 Cc. of water, successively for 3 times, to the chloroform-ether solution and shake, the aqueous layer being separated and filter, each time, through the same filter-paper which is finally washed with water, then mix the whole filtrates and washings, and make the mixture to 100 Cc. by adding water. To 50 Cc. of the solution thus prepared, add 1 Cc. of alcohol, in which a small piece of hematoxylin has been freshly dissolved, and titrate the resulting yellowish solution with decinormal potassium hydroxide solution, then not more than 4.3 Cc. of the latter solution should be required in order to color it immediately bluish-violet; and 5 Cc. of the solution left in the flask, after being mixed with 1 Cc. of chlorine water, should acquire a beautiful green color by adding ammonia water.

5. Hungarian Pharmacopoeia.

2.5 Gm. of powdered cinchona bark are shaken with 15 Cc. of water and then mixed with 25 Gm. of chloroform and 50 Gm. of ether. 5 Cc. of fifth-normal caustic soda are added and the mixture shaken at intervals during ½ hour. 60 Cc.* of the ethereal liquid (= 2 Gm. of bark) are then filtered into an Erlenmeyer flask, the menstruum is evaporated and the residue is treated with 2 or 3 Cc. of ether which is evaporated also. The residue is then dissolved in 30 Cc. of alcohol and after the addition of one or two drops of lacmoid solution, tenth-normal hydrochloric acid is added until the blue color has changed to red. 3.8 to 4.0 Cc. of tenth-normal hydrochloric acid should be used.

2½ Gm. of cinchona bark are mixed in a flask of 200 Cc. capacity with 5 Cc. of diluted hydrochloric acid and 17 Cc. of water. The mixture is then heated for fifteen minutes on a steam-bath, and after cooling, 50 Gm. of ether and 25 Gm. of chloroform are added and the mixture shaken well. Then 4 Gm. of caustic potash solution (33½ per cent.) are added, the mixture shaken well for ten minutes, and after the addition of traga-canth, shaken again. The flask is allowed to stand for five minutes and

* Should read 60 Gm.
00 Gm. of the clear ether-chloroform solution is filtered through a pledget of cotton into a flask and the menstruum distilled off at once. The residue is treated three times with 5 Cc. of ether which is evaporated each time. Then the residue is dissolved with the aid of gentle heat in 10 Cc. of absolute alcohol, mixed with three drops of hematoxylin solution and 10 Cc. of water and titrated with tenth-normal hydrochloric acid until a red-brown color is obtained in the aqueous liquid. Then 30 Cc. more of water are added and the titration continued until a lemon-yellow color is produced. Not less than 4.3 Cc. of tenth-normal hydrochloric acid should be used.

7. Dutch Pharmacopoeia.

6 Gm. of powdered cinchona bark are mixed with 2 Gm. of calcium hydrate and 90 Cc. of chloroform and 12 Cc. of ammonia water. The mixture is then shaken frequently for three hours and 75 Cc. of the chloroform, equal to 5 Gm. of powdered cinchona bark, are filtered and evaporated to dryness. The residue is dissolved in a few Cc. of alcohol and 20 Cc. of tenth-normal hydrochloric acid are added. The acid solution is filtered through a wetted filter, and flask and filter washed with small quantities of water until the filtrate has a neutral reaction. The total amount of filtrate should not exceed 100 Cc. The excess of acid is titrated back with tenth-normal alkali, using hematoxylin as an indicator. A persistent cloudiness shows the end of the reaction. Not more than 10 Cc. of caustic alkali should be used.

8. Belgium Pharmacopoeia.

12 Gm. of powdered cinchona bark in No. 30 powder previously dried at 100° C., are then mixed in a bottle of 200 Cc. capacity with 180 Gm. of chloroform and 10 Cc. of ammonia water, and allowed to stand for three hours, shaking frequently and vigorously. Then 3 Gm. of gum tragacanth are added, followed by 20 Cc. of water. After strong shaking the mixture is rotated until the powder has balled together and the chloroform separated as a clear liquid. The mixture is then allowed to stand for one hour and the chloroformic liquid is filtered. The chloroform from 150 Gm. of the filtrate is distilled off, the residue dried, then dissolved in 20 Cc. of chloroform and the solution decanted in a separator. The flask is rinsed twice with 5 Cc. of chloroform and once with 60 Cc. of ether. Then 25 Cc. of tenth-normal hydrochloric acid are added and the mixture shaken well. After clearing, the aqueous liquid is filtered and the ether-chloroform solution washed three times with 10 Cc. of water which is also filtered. The combined acid liquids are then diluted with water to exactly 100 Cc. To 50 Cc. of this solution 1 Cc. of an alcoholic solution of hematoxylin is added, and then tenth-normal sodium hydrate solution until the yellow color changes to bluish-violet after strong shaking. The factor used for cinchona alkaloids is .0309.

7½ Gm. of powdered cinchona bark are transferred to a bottle of 200 to 300 Cc. capacity and shaken with 150 Cc. of ether. Then 10 Cc. of diluted caustic soda (2 parts of caustic soda solution and 3 parts of water) are added and the mixture shaken well for ½ hour. After the addition of water the mixture is shaken well, and after perfect clearing the ethereal liquid is filtered through a dry filter. 100 Cc. of the filtrate are distilled, the residue is taken up in 25 Cc. of tenth-normal hydrochloric acid, the mixture heated on a water-bath gently, and filtered after cooling. Flask and filter are then washed with water and the excess of acid titrated with tenth-normal caustic potash in the usual way, using hematoxylin as indicator.

Mix 20 Gm. of red cinchona bark, in No. 60 powder, with 6 Gm. of calcium hydroxide, slightly moisten the powder with 20 Cc. of water; mix the whole intimately in a small porcelain dish or mortar; allow the mixture to stand for an hour or two, when it will present the character of a moist dark brown powder, in which there should be no lumps or visible white particles. Transfer this powder to a suitable flask fitted with a small reflux condenser, add 130 Cc. of benzolated amyl alcohol, boil them together for about half an hour, decant the liquid onto a filter, leaving the powder in the flask, add more of the benzolated amyl alcohol to the powder, boil and decant as before; repeat this operation a third time; then turn the contents of the flask onto the filter, and wash by percolation with more of the benzolated amyl alcohol until the bark is exhausted. Introduce the collected filtrate, while still warm, into a stopped glass separator; add to it 2 Cc. of diluted hydrochloric acid, mixed with 12 Cc. of water; shake them well together, and when the acid liquid has separated this may be drawn off, and the process repeated with water slightly acidulated with hydrochloric acid, until the whole of the alkaloids have been removed. The Br. Ph. then directs the determination of the combined quinine and cinchonidine by precipitating the alkaloids with a solution of Rochelle salt. This was not carried out in these experiments, as comparative figures for the total alkaloids were desired. The acid solution, therefore, was made alkaline with ammonia and the alkaloids extracted by shaking out with chloroform. The chloroform solutions were combined in a tared Erlenmeyer flask, the chloroform evaporated and the residue dried to a constant weight.

11. Italian Pharmacopoeia.

Ten Gm. of cinchona bark in a very fine powder are mixed with 12 Gm. of calcium hydrate and 100 Cc. of (90 per cent.) alcohol. The mixture is then heated to boiling for one hour in a flask provided with a condensing tube. After allowing to cool, sufficient alcohol is added to make
the total weight of the mixture 190 Gm. After shaking well, the liquid is allowed to clear and is then filtered. 100 Cc. of the filtrate, which has a b. gr. of .84, representing 5 Gm. of the bark, are transferred to a porcelain dish, the measuring cylinder is washed three times with small amounts of alcohol which are also added to the dish, and after the addition of 20 Cc. of 1 per cent. sulphuric acid, the aqueous alcoholic liquid is evaporated until 10 Cc. of residue are obtained. After allowing to cool 10 Cc. of water are added and the mixture filtered into a separatory funnel, washing the bowl and filter with distilled water, which is also filtered into the separator, until one drop of the filtrate gives no reaction with picric acid. The solution in the separator is then shaken for ten minutes with 50 Cc. of chloroform after the addition of a 10 per cent. solution of sodium hydrate to produce an alkaline reaction, and the chloroform is transferred to a tared flask and distilled off. The aqueous liquid is then shaken out once more with the recovered chloroform, which is added to the residue in the flask. The menstruum is then distilled off and the residue dried at 110° C. to a constant weight.

12. French Codex.

Transfer to a glass-stoppered bottle of 1 liter capacity, 30 Gm. of cinchona bark previously dried at 100° C. Add to this a previously prepared mixture of 35 Cc. of ammonia water (20 per cent.) and sufficient alcohol to form a total volume of 180° C., shake well for one hour from time to time, and add 720 Cc. of ether, shake the well-stoppered bottle occasionally during six hours, then filter the ethereal liquid through a folded filter until 750 Cc. (equal to 25 Gm. of cinchona) are obtained. Distill off the ether in a convenient flask. After the ether is driven over, the distillation is continued until a part of the alcohol is distilled. The remaining liquid is then transferred to a flask of 125 Cc. capacity and the distillation is continued until no more liquid is left. The last traces of alcohol are then removed by placing the flask in boiling water. Dissolve the residue in a small quantity of water and 40 Cc. of dilute hydrochloric acid, by heating gently on a water-bath, and allow to cool. Filter the acid solution through a plain filter of 65 Mm. diameter into a separator of about 250 Cc. capacity. Wash the flask and filter completely with water and add the water to the filter. Add to the separator 125 Cc. of chloroform, then sufficient ammonia water to produce an alkaline reaction, or until the odor of ammonia is perceptible. Shake well and draw off the chloroformic solution into another separator. The ammoniacal liquid is treated twice with 125 Cc. each of chloroform. Wash the combined chloroformic solution by shaking with 10 Cc. of distilled water, which after separating is drawn off and rejected. The chloroformic solutions are then distilled until 200 Cc. of chloroform have distilled over. The remaining chloroform is transferred to a graduated flask of 250 Cc. capacity and the dis-
tilling flask washed with sufficient chloroform to obtain 250 Cc. of chloroform solution. After mixing well, 50 Cc. of this solution, corresponding to 5 Gm. of the cinchona, are transferred to a tared flask of about 90 Cc. contents, the chloroform distilled off, the residue dried at 100° C., and then weighed.

25 Gm. of the powdered bark, 25 Gm. of alcohol, 15 Gm. of ammonia water and 200 Gm. of ether are mixed together, and the mixture is allowed to stand over night in a cool place with occasional shaking. 150 Gm., equal to 15½ Gm. of the bark, are then transferred to a flask and the ether distilled off. The alcoholic liquid is made strongly acid with normal sulphuric acid and after the addition of 20 Gm. of water the alcohol is evaporated off and the remainder filtered. The filtrate is divided into two equal parts; one part is made strongly alkaline with ammonium hydroxide and the separated alkaloids collected on a tared filter and dried at 100° C. to constant weight.

The quinine is determined in the other portion.

No assay process is given.

Comments.

By examining a sample of opium by the different methods, the following results were obtained, all calculated for morphine with water of crystallization.

As will be seen from the above directions, the U. S. P., the German, Swiss, Swedish, Hungarian, Danish, Austrian and Belgian Pharmacopoeias use only water for exhausting the opium and precipitate the morphine with ammonia water.

While in the U. S. P. no special provision is made for removing the narcotine, the German Pharmacopoeia uses for this purpose a sodium salicylate solution, while the other pharmacopoeias use normal ammonia water.
For holding the other alkaloids in solution, in most of the pharmacopoeias alcohol-ether is used, but in the Swedish, Hungarian, Austrian and Belgian pharmacopoeias, acetic ether.

The varying results obtained by the different methods, which in their fundamental idea are nearly all the same, depend largely upon the time allowed for the morphine to crystallize out. While the U. S. P., German and Danish pharmacopoeias allow the mixture to stand for 24 hours, the Swedish, Austrian and Belgian pharmacopoeias direct filtering at once, and the results therefore are correspondingly low. Similar results are obtained by the Swiss pharmacopoeia, in which only $\frac{1}{2}$ hour is allowed and also by the Hungarian pharmacopoeia, where 10 minutes are considered as sufficient for the morphine to crystallize out.

The high results obtained by the U. S. P. are apparently due to the thorough exhausting of the opium, to the longer time allowed for the morphine to crystallize out, and to the fact that the morphine is crystallized from a more concentrated solution. While in all the other pharmacopoeias the proportion of the opium to menstruum is about 1 to 10, in the U. S. P. 3.4 parts of liquid represent one part of opium. The chances for the morphine to remain in solution are, therefore, less in the U. S. P. than in the other pharmacopoeias.

The methods which depend on the exhaustion of opium by lime water, that is, by mixing the opium with slaked or unslaked lime and extracting this mixture with water, are the following: The British, Dutch, Japanese, Spanish pharmacopoeias and the French Codex. In these methods it can also be noticed that when the morphine is allowed to crystallize for at least 16 hours, the results are considerably higher, than when only a short time is allowed for crystallization, as may be seen in the results obtained by the Spanish pharmacopoeia. In all these methods also the proportion of opium to menstruum is about 1:10.

The low results obtained by the Dutch pharmacopoeia cannot be explained. They may be due to the small amount of opium taken for the determination.

The comparatively high results obtained by the method of the French Codex are due to the impurities. The morphine obtained is of a rather dark color.

The most unsatisfactory method is that of the Italian pharmacopoeia. The results are very low, and this is due to the fact that a part of the morphine is destroyed by evaporating the salt solution to dryness. We have noted at times that when an aqueous extract of opium is evaporated to dryness on a water-bath the amount of morphine is much lower than when the extract is evaporated only to a syrupy consistence. Besides giving low results, the morphine obtained by the Italian pharmacopoeia method is of a very dark color, and cannot be purified even by prolonged washing with benzene.
In connection with the Pharmacopœia Japonica, it may be said that the wording given in this paper is the same as that given in the English edition of the Japanese Pharmacopœia.

The method taken from the Spanish pharmacopœia is a close translation of the original text. Inasmuch, however, as the determination of morphine cannot be carried out in the manner prescribed, the method was modified on a more rational basis.

_Nux Vomica._

No assay processes are given in the British and Spanish pharmacopœias.

In two of the pharmacopœias, the Dutch and Italian, it is directed that the nux vomica be previously deprived of its fat by extracting with petroleum ether. In all the pharmacopœias, mixtures of ether-chloroform in various proportions are used, and this accounts for the rather uniform results which were obtained by applying the different methods.

The comparatively low results obtained by the methods of the Austrian Pharmacopœia and of the French Codex may be due to the fact that only two shakings are used for removing the alkaloids from the alkaline liquor.

The still lower results obtained by the method of the Italian Pharmacopœia are caused by the use of only one shaking with ether-chloroform, which, as is well known, does not remove all the alkaloids.

The high results obtained by the Swedish and Danish pharmacopœias are due to the fact that it is impossible to obtain a clear filtrate of the ether-chloroform mixtures. Some of the caustic potash solution seems to go through the filter and consequently renders the results high. In all, six determinations were made, but high results obtained in each case.

The Belgian Pharmacopœia directs that the nux vomica be previously exhausted with 70 per cent. alcohol, and the resulting extract treated with ether-chloroform, etc.

_Cinchona._

The following results were obtained:
As will be seen from the foregoing, the methods of exhausting the bark vary considerably in the different pharmacopoeias. The U. S. P. and the Austrian use ether, chloroform and ammonia, while the German, Japanese and Hungarian pharmacopoeias use ether, chloroform and caustic soda. The Swiss pharmacopoeia has adopted the well-known Fromme method of extracting the bark with acid, while the Dutch pharmacopoeia uses chloroform, calcium hydroxide and ammonia, the Swedish pharmacopoeia ether and caustic soda, the British pharmacopoeia calcium hydrate and benzolated amyl alcohol, the Italian pharmacopoeia calcium hydroxide and alcohol, and the Danish pharmacopoeia and the French Codex alcohol, ether and ammonia.

The high results obtained by the Dutch and Belgian pharmacopoeias are apparently due to the thorough exhaustion of the alkaloids by the use of chloroform, which is the best solvent for the cinchona alkaloids.

The acid extraction adopted by the Swiss pharmacopoeia gives higher results than that of the U. S. P., when high grade barks are examined. In barks containing about 5 per cent. of alkaloids both methods give results nearly alike.

The large amount of Cinchona bark used by the French Codex is unnecessary, and should be reduced. The French Codex and the Danish pharmacopoeia also direct that the quinine be determined, but this was not done; nor were the ether-soluble alkaloids determined as directed in the U. S. P., nor the mixture of quinine and cinchonidine as given in the British pharmacopoeia. The mixture of total alkaloids obtained by the method of the latter is very dark, and this method without doubt is the worst of all, not only giving low results, but also on account of using amyl alcohol for the extraction.

The low results obtained by the method of the Japanese pharmacopoeia are due to the fact that insufficient ether-chloroform is used to hold the alkaloids in solution.

The low results obtained by the process of the Italian pharmacopoeia must be due to an insufficient exhaustion. Six experiments were made and invariably low results were obtained.
The low results of the process of the Danish pharmacopoeia are due to
the fact that a part of the alkaloids is retained in the alkaline liquid.

It is interesting to note that by the process of the Swedish pharma-
copoeia, in which only ether is used, such high results are obtained as re-
ported. This can be explained by the fact that ether under normal condi-
tions does not eliminate the cinchonine altogether, a fact which has been
demonstrated in numerous experiments by the irregular results obtained
by the U. S. P. method for determining the ether-soluble alkaloids.

THE CHAIRMAN: These two papers—the one by Mr. Lyons, and the other by Mess.
Dohme and Engelhardt, are now before you for discussion. Are there any comments to
be made, or questions asked?

MR. VANDERKLEED: I did not hear the earlier part of Mr. Lyon’s remarks, but I
agree with him as to the desirability of checking the chemical assay by means of the
physiological test. I question very much, however, whether greater accuracy can be ob-
tained by means of the physiological test of any kind, from the fact that different oper-
ators will report different results from the same preparation; and not only that, but differ-
ent operators, under different conditions will report different results. So it is rather an
unreliable method of checking the chemical assay. After the symposium this after-
noon, of physiological tests, I think that question can be brought up and perhaps discussed.

Then in regard to Mr. Dohme’s paper, I would like to ask him about the use of C. P.
Ether, instead of ether and water, whether he did not find it true that lower results were
obtained?

MR. DOHME: I did, yes.

MR. STEVENS: Mr. Chairman, I always like to agree with my old friend Mr. Lyons,
but there are occasional points where we must differ, and certainly one of them is on
this aconite question. I have done considerable work upon this. I do not see how it
is possible to give two methods in the Pharmacopoeia for one preparation. If you do,
which one are you going to depend upon? One or the other of those methods must be
accepted as the standard. If you assay by the chemical method, and then you say you
are going to check it by the physiological method, then why not do away with the chem-
ical method and take your physiological method?

The physiological method is absolutely unreliable, as has just been pointed out, in the
hands of different individuals. I have found advanced students, familiar with the taste
of aconite, who would get fairly good results; whereas I found others who could hardly
detect any effect from the same aconite even in one-fifth, or one-tenth strength of that
which was reported by others. Then again, under different conditions the same individ-
ual will obtain different results.

And still further, I want to say in regard to the application of the chemical test to the
drug, that I have obtained drugs under all sorts of conditions as to age and some so
worm-eaten that the tubers would not hold together, yet the variation in age could be
told by the chemical test. In case heat is used there is no doubt a change that will give
high results by the chemical assay method, even after the physiological results have
disappeared, but preparations of aconite are no longer made by heat.

Now then, I want to say a little something on that old bugbear question, the Opium
Assay. Mr. Lyons has pointed out one of the principal objections to the use of the lime
assay, for the assay of opium, and that is the aliquot part. I think we all recognize
that we would like to do away with the aliquot part wherever it is possible to do so. He
was also kind enough to state that, after all, it did not influence the results more than
about a fifth of one per cent. in the final result; so that does not stand in the way very much. In the lime method we are dealing with an aqueous solution in which there is very little loss. On the other hand, it has been used quite extensively in preparations where we use a volatile liquid like ether, chloroform and alcohol, and mixtures of these, where there is not only rapid evaporation, but where there is concentration, or condensation.

There was another question he brought up—in regard to the removal of the crystals, in using counterpoise filters. Wherever filters are counterpoised, and used dried before weighing, you will find that invariably the outer filter will contain impurities which have been carried to the surface by evaporation. That is a fact that has been pointed out years ago in the manufacture of certain preparations. J. U. Lloyd stated, that in drying crystals, he preferred to hang them up, and not spread them out, and let them dry, so the impurities would come to the outside. I have not made experiments to prove it—but I am inclined to think the error introduced by the use of counterpoised filters will be greater than by removing the crystals as in the opium assay.

In regard to determining the impurities in the morphine by the pharmacopoeia method, Dr. Lyons spoke of that and I thought he covered it very nicely, but I want to emphasize it. You will find that lime water will dissolve a lot of impurities. The test was introduced solely for the purpose of determining the purity of the morphine, with the idea of dissolving out the morphine and leaving the impurities on the filter. Take morphine as you find it in the pharmacopoeia method, where the result gives you a dark colored residue of morphine, treat it with lime water and you will find that a great deal of that colored matter will be dissolved with the morphine. I saved the filtrates in a few cases, and afterwards evaporated them down to dryness, and found a very fine, dark residue, which could not be due to lime, or morphine. It is a well known fact, I think, to those who assay opium, that the color is no criterion of the purity of morphine in the assay by the pharmacopoeia method. Those who have worked on the U. S. P. revision committee remember one sample that gave the largest amount of impurities of any assay we obtained by the pharmacopoeia method, and yet it was almost white. It is very often the case that the very whitest morphine residue you get is apt to be the least pure, because it consists of impurities which are colorless.

The Chairman: I want to call attention to the fact again, that a general meeting has been called for 12 o'clock, and we have been requested to adjourn early, so if members will make their remarks brief and to the point, it will enable us to get through by the time the general meeting is held.

Mr. Lyons: I have just a few words to say. Of course, when I say that with our present knowledge of the subject, it is not right for us to accept unqualifiedly the results of chemical assays in aconite, how shall we check the result? It is right for us in any case to attempt to show the purity or impurity of our product. Some method of checking by physiological test is certainly justifiable. It does not give you two standards; it simply says that although your chemical assay has given you what the Pharmacopoeia requires as a standard, the physiological test has not.

I wish to say a word on some of the processes of other pharmacopoeias. Most of the new assay processes follow the German Pharmacopoeia in attempting to get rid of the objectionable impurities in the morphine, by first adding a very small amount of ammonia, which precipitates at once that impurity, filtering rapidly, and then adding a larger amount of ammonia.

I should like to have the point especially brought out, if possible, in Mr. Dohme's paper, whether in processes in which that method is used, lower results or practically the same results are obtained. From what I have seen, myself, the results seem to be a
little bit lower, and yet not so much as to cause us to reject the process, except that in inexperienced hands we are liable to get some losses of morphine.

Mr. Dohme: In reply to Mr. Lyons I would say those processes all give lower results, but only about two-tenths per cent., which was probably within the range of error, I should say, and seemed to indicate that it did not make as much difference as we expected; but I agree with Mr. Lyons that it is a dangerous thing to introduce for general use, because it is liable in some hands to give very discordant results. I am very glad Mr. Lyons made the last remarks he did, because I think they prove what I said before. He simply uses his physiological test for quality and not quantity; then if the drugs are spoiled by age, what is the value of the physiological test?

The Chairman: When we opened this meeting, we were without a quorum. I see that we now have a quorum present, and it is a good time for us to vote for officers.

The following named gentlemen were placed in nomination, and on motion, the nominations closed, and the unanimous vote of the Section cast for their election, namely: Mr. A. H. Clark, of Chicago, Chairman; Mr. William O. Richtmann, of Satsuma Heights, Fla., Secretary.

The Chairman: Unfortunately, some of the papers for this morning came in too late to be printed. The next paper on the program would be of infinitely more interest to you if it were printed, and as Dr. Seidell is not here, I think we had better pass the paper, reading it by title only, and proceed. The paper is entitled The Distribution of Alkaloids between Immiscible Solvents, and its Bearing upon Assay Processes.

The Chairman: The next paper we have is by Mr. A. H. Clark, on the U. S. P. Methods of Assay of Belladonna Extracts and Belladonna Plasters.

Mr. Clark here read his paper as follows:

ON THE ASSAY OF BELLADONNA PLASTER AND EXTRACT OF BELLADONNA.

A FEW CRITICISMS AND SUGGESTIONS.

A. H. CLARK.

In attempting to assay belladonna plaster of commerce, following strictly the directions of the U. S. P., I met with some serious difficulties and found that certain modifications of the process laid down there would greatly facilitate the work of assay and bring about more uniform results.

In view of the coming revision of the Pharmacopæia I offer these criticisms and suggestions in the hope that they will aid in working out a more satisfactory assay method than that now official.

Before entering on the discussion of these points I wish to say that the method of the U. S. P. was tried upon plasters prepared by myself from start to finish, belladonna extract, lead plaster and all, and to my surprise I found that the method could not be applied. The lead plaster dissolves in the chloroform, and some of it, at least, remains until the sulphuric acid is added in the shaking out of the alkaloid, and is then decomposed, the fatty acids separating and floating on top or partly emulsifying, and the lead precipitating as lead sulphate, all of which results in a mixture from which
it is practically impossible to separate the acid solution. There being no lead plaster in the commercial article, these objections do not hold good.

The first objection to the U. S. P. process I found to be in the directions to add the plaster to a suitable beaker containing 25 Cc. chloroform and 3 Cc. ammonia water. When this is done the ammonia water is immediately absorbed, in part at least, by the cloth of the plaster and renders the subsequent removal of the plaster extremely difficult, a greatly increased quantity of chloroform being necessary to complete the washing, and even then the cloth is highly colored and contains quite a large amount of the plaster.

If the directions to continue the washings with chloroform, adding 1 Cc. ammonia water, are followed, 4 Cc. ammonia water will be carried into the separator. This amount of ammonia water will require about 23 Cc. of normal sulphuric acid to neutralize it. It is obvious, then, that there will be required of the mixture directed (normal sulphuric acid 40 Cc. and water 60 Cc.) about 60 Cc. before the ammonia water is neutralized. One might extract with 20, 10, 10, etc., Cc. of the mixture, test the fourth or even the fifth extraction as directed with Mayer’s solution, and find no alkaloid, not, however, because it was all extracted in the first portions, but because the solution is still alkaline.

The directions to test with Mayer’s reagent are objectionable because of the alcohol which necessarily is carried along in the extraction, and which inhibits the delicacy of the test. This objection holds good with Wagner’s reagent also, but I prefer the latter, as it seems to me, under the circumstances, to be more sensitive.

The remaining directions of the U. S. P. seem to be very satisfactory.

To overcome the directions mentioned above I have adopted the following procedure:

Take about 10 Gm. of the plaster (one commercial plaster weighs this), after removal of the thin gauze from the face of the plaster as well as the large protecting sheet from the back, cut it into four equal parts, and these again into strips about one quarter inch wide. Place it in an Erlenmeyer flask of about 100-Cc. capacity, which is fitted with a good cork. Add 25 Cc. chloroform and shake gently for two or three minutes. Decant the chloroform solution into a second Erlenmeyer flask of about 250 Cc. capacity, fitted with a good cork. Repeat the washing of the cloth with another portion of chloroform of 25 Cc. and decant to the large flask as before. Continue the extraction of the cloth with portions of chloroform of 10 Cc. each until 100 Cc. in all have been used. To 80 Cc. of alcohol add 2 Cc. ammonia water and wash the cloth with this mixture in portions of 10 Cc. each, adding the washings to the large flask each time and shaking well after each addition. Allow the flask to stand a few minutes and decant the clear liquid to a separator of 250 Cc. capacity and wash the flask and precipitated rubber with several small portions of alcohol,
using in all about 15 Cc. To the separator add 20 Cc. normal sulphuric acid and shake thoroughly. After complete separation draw the lower chloroformic layer into a beaker and filter the acid liquid through a small plug of cotton into a second separator of about 150 Cc. capacity. Return the chloroformic solution to the first separator, repeat the shaking out with a mixture of 5 Cc. normal sulphuric acid and 10 Cc. water, collecting the acid liquid in the second separator as before. Repeat the extraction in the same manner until a portion of the acid liquid does not precipitate with Wagner's reagent, even on standing 10 minutes. Render the acid liquid in the second separator alkaline with ammonia water and extract the alkaloids with four successive portions of chloroform of 25, 15, 10, 10 Cc. each, filtering each portion through a small plug of cotton into a beaker. Evaporate the chloroform by aid of a gentle heat, and to the residue add a slight excess tenth-normal sulphuric acid (from 2 to 2.5 Cc.), noting the exact amount. To the residue add 10 drops chloroform, and after all has dissolved expel the chloroform by aid of a gentle heat. Add 5 drops cochineal T. S. and determine the excess of acid with fiftieth-normal potassium hydroxide V. S. Divide the Cc. of fiftieth-normal potassium hydroxide V. S. by five, subtract this quotient from the Cc. tenth-normal acid added, multiply the difference by 0.0287 and divide this product by the weight of plaster removed from the cloth. The quotient multiplied by one hundred gives the per cent. mydriatic alkaloids in the plaster.

After washing the cloth as directed, it is placed in a tared weighing bottle and dried at 100° C. and its weight subtracted from the original weight taken. The remainder is the weight of plaster on the cloth.

This procedure gives a cloth that is perfectly white and weighs an amount appreciably less than when treated by the U. S. P. method. The weight of the cloth varies but little, twenty-five recent assays giving an average weight of 2.997 Gm., the highest weight being 3.0560 and the lowest being 2.9083 Gm. If a plaster weighs ten Gm., a variation of 0.5000 Gm. in the weight of the cloth means a difference of about eight per cent. in the amount of alkaloid found. This might be the cause of considerable error in the final report on the assay of belladonna plaster.

**Belladonna Extract.**

In the assay of extract of belladonna the directions of the U. S. P. to dissolve the extract in a mixture of alcohol, water, ammonia water and chloroform, if followed literally, result in a very bad mixture. The chloroform being heavier than the other liquids settles to the bottom of the beaker and surrounds the extract which it does not dissolve, and vigorous and long-continued stirring is necessary to bring the extract in contact with the water, and alcohol mixture sufficiently to dissolve it. To overcome this objection, I have proceeded, as follows:

To the belladonna extract contained in a suitable beaker add 15 Cc. of
a mixture of alcohol and water, two to one by volume, and warm the mixture gently on a water bath, stirring until completely dissolved. Transfer the mixture to a separator and rinse the beaker with 10 Cc. of the alcohol and water mixture added in small portions at a time. Transfer these washings to the separator and add also 2 Cc. ammonia water. The procedure from here on is the same as that directed in the U. S. P.

In commercial extract of belladonna root and possible of scopola root it is convenient to increase the volume of the alcohol and water mixture in which the extract is dissolved and also the volume of chloroform to prevent the formation of troublesome emulsions.

*University of Illinois School of Pharmacy, Chicago, Ill.*

MR. PUCKNER: Mr. Chairman, the paper I think has brought out one point very prominently: the greater need, apparently, of describing the assay processes in the Pharmacopoeia. The wording for the assay of the extract of belladonna, as it was submitted to the proximate Assay Committee, merely stated that alcohol, chloroform and water would be used to dissolve the extract and transfer it to the separator. It was presumed that those who use the processes would know how to use these solvents to effect that transfer. Later, in wording the method for the Pharmacopoeia it was worded in such a way as to mislead those who tried to follow the processes accurately. The same thing applies to the assay of the belladonna plaster, where the amount of acid is barely sufficient to neutralize the ammonia. The intention, of course, was to use that acid first to neutralize the ammonia and then complete the extraction with the water that was left over. It seems to me as these Pharmacopoeia methods must be followed accurately, it is necessary, in order to avoid different results, that the details must be made more explicit.

MR. VANDERKLEED: It seems to me that it will never be possible in the Pharmacopoeia to give explicit directions for carrying out an assay which will in different hands yield exactly concordant results. I think one of the troubles in the Pharmacopoeia is that we try to give too explicit directions, and do not give enough leeway. What we need more particularly is a very good series of general directions on assays, to apply to all of them, and leave many of the details to individuals.

MR. KEBLER: I would simply say that if we had plenty of men in this country who were experts, or who were qualified to apply these methods based on general directions, I think that would be very well; but even with the details that we now have, granting that some of them are a little off-color, the results are far from concordant; and as I will try and bring out in a paper subsequently, what to me seems important is to have the methods given in detail as far as possible, and instruct the man that does the work to follow those details, and not let him exercise his own ingenuity, as that, in my opinion, is what causes the trouble.

MR. LYONS: The paper is a very valuable one; not in itself, that is, not because the subject of assay is a particularly important one, but because it develops a weakness of a number of our assay processes in the Pharmacopoeia, in which the directions have failed to be perfectly explicit. It emphasizes what I have laid down here as one of the general principles, in the paper I have read, that we should have in the Appendix of the Pharmacopoeia, very detailed and explicit directions for the general method of alkaloid assays. That will do away with many of these difficulties.

THE CHAIRMAN: The next paper is by Mr. Kebler, and before taking that up I would
like to call attention again to the fact that it is now ten minutes to 12, and we have been requested to adjourn promptly at that hour, so as to give members who desire to do so, an opportunity to attend the general session. I do not, myself, think it is fair that those who do not care to attend the general session should be deprived of continuing with this meeting, and so I will entertain a motion that we remain in session until we dispose of our morning's program.

Mr. Stevens I do not think it requires any formal motion; of course any one who desires to attend the general session will feel at liberty to withdraw at any time he sees fit.

The Chairman: I would state that we have had permission from our Council to continue the session until we are through, and those of you who wish to attend the general session will please remember that it meets at 12 o'clock.

Mr. Kebler here presented his paper on "The Present Status of Drug Assaying."

THE PRESENT STATUS OF DRUG ASSAYING.

By Lyman F. Kebler, Chief Drug Division Department of Agriculture.

In 1905 in a paper entitled "Outlines for the Sampling of Drugs and Chemicals" I called attention to the importance and value of procuring average representative samples before undertaking a chemical investigation. Extended observations since that time confirm the views expressed in that paper, both as to methods of sampling and the imperative necessity of securing representative samples.

During the past few years we have been called upon to apply the pharmacopoeial and other methods of analysis to commodities imported into the United States and subject to interstate commerce. In many instances the samples under investigation represented transactions of considerable magnitude. Importers and dealers did not as a rule submit without protest and verification to some of our findings. So far, however, our results have stood the test. I recall only a single exception where there was a material difference between the findings of the Bureau of Chemistry and the results obtained by the chemist of the importer, and that was in favor of the commodity, that is, the first results were higher than the average of a more extended examination. The goods were released on the first findings. The importer, however, was annoyed because of the fact that a more extended examination of the commodity showed that on the whole the alkaloidal content of the material was below the standard. It was his desire on this ground to have the Department take adverse action and exclude the importation. The findings, however, had been reported, the goods released, and it was therefore impossible to comply with the request.

The above, however, does not mean that the results of the Bureau of Chemistry and the chemist for the importers are always in concordance. In fact, it is almost always necessary to allow for certain variations. On the whole, however, the results obtained by the present pharmacopoeial
methods for determining the various alkaloidal constituents present in potent drugs are fairly satisfactory, considering all of the disturbing factors encountered.

The question naturally arises as to the permissible variation in analytical work of this character. It must be stated in the outset that it is impossible to draw a hard or sharp line of demarcation for any commodity. It is always necessary to take into consideration the nature of the article, the character of the goods, and other factors that may arise.

During the past six years the Association of Official Agricultural Chemists has through a referee, who has been and now is the Chief of the Drug Division, continued a series of co-operative investigations along certain lines. These results have been published in the "Proceedings" of the Association of Official Agricultural Chemists, and serve as a basis for arriving at reasonable variations obtained by workers conducting their analyses in different sections of the country. It is a well-known fact that two or more chemists working side by side or under the same management obtain more concordant and uniform results than those working separately and apart from one another; for example, Dr. LaWall and myself, during a number of years working side by side, frequently checked each other's findings with the result that as a rule there was very little difference, but if a portion of the same article was examined by a chemist located in some other laboratory, his findings frequently varied materially from our results.

In order to arrive at some conclusion as to the variation that should be permitted on results obtained by various workers on different commodities, I have carefully studied the co-operative results obtained and published since the year 1906. The first extensive co-operation work in pharmaceutical products of the character under consideration, to my knowledge, was undertaken by a committee on indicators of this Association in 1905, and continued for the years 1906 and 1907. From the title it can readily be seen that the chief purpose of the investigation was not for the purpose of determining the amount of variation obtained by the several workers, but a test of the value of the several indicators. This in itself makes the work of even more value. In order to arrive at fair results, it is usually necessary to make duplicate analysis and report the average findings. From this it can readily be seen that there is always an upper and lower factor. In order to provide for this it has been our practice to allow variation above and below the average; for example, if a number of observers report certain figures on a sample of opium and the total variation between the maximum and minimum is 10 per cent., based on the average, the variation would be 5 per cent. above and 5 per cent. below this average. In practice it has been found that this sliding scale, as it may be called, works very satisfactorily. By applying this method to the results published by the committee on indicators, it will be found that
when the examinations were restricted to pure material, viz., the alkaloids of atropine, brucine, morphine, and strychnine, the variation from the average did not exceed 2½ per cent. The same also holds true to determining the per cent. of pure morphine present in crude morphine by titration.

In the case of ipecac one set of workers reported results which very nearly came within a 5 per cent. variation. In another set of results, however, the variation amounted to approximately 10 per cent. The variation of the results obtained in another line of experiments by certain workers is approximately 10 per cent., but the subsequent year the variation is as high as 15 per cent.

In the case of nux vomica the variation in three different reports was less than 10 per cent., and in two other reports it exceeds slightly 15 per cent., while in two additional reports the variation reaches almost 20 per cent.

In the case of coca and belladonna leaves the variation is as high as 35 per cent., a range which is entirely too great.

A review of the work done by the Association of Official Agricultural Chemists shows a variation for opium based on table 1 of 5 per cent.; table 2, 7½ per cent.; table 3, 5 per cent.; table 4, 7½ per cent.; table 5, 5 per cent.; table 6, 7½ per cent.; table 7, 5 per cent.; table 8, variations between 5 per cent. and 10 per cent. In the case of cinchona, table 9, the variation is 15 per cent., and ipecac and nux vomica are 10 per cent.; the variation for aconite leaves by the Pharmacopœial method is 25 per cent.; for the same drug by another method, 7½ per cent.; aconite root, 20 per cent. by the Pharmacopœial method and 25 per cent. by another method based on aliquot parts; belladonna leaves by Pharmacopœial method, 20 per cent.; by another method based on aliquot parts, 10 per cent.; belladonna root, by Pharmacopœial method, 15 per cent.; by a second method based on aliquot parts, 5 per cent. In the case of cinchona (yellow) by the same table the variation for total alkaloids by the Pharmacopœial method was less than 1 per cent. The ether-soluble alkaloid, however, by the same method is 15 per cent.; the total alkaloids determined by a second method varied slightly over 10 per cent., whereas the ether-soluble alkaloidal variation was less than 1 per cent. In the case of red cinchona the story is about the same. Coca leaves, variation by both methods is approximately 25 per cent. Colchicum corm, Pharmacopœial method, varies nearly 25 per cent.; determinations made by a second method show a variation of less than 7½ per cent. In the case of colchicum seed the variation for the Pharmacopœial method was slightly less than 25 per cent., but the variation with a second method was over 50 per cent.

I have also made a careful study of the results obtained by the Pharmacopœial sub-committee on assaying. I present them below without comment, allowing each reader to make his own deductions.
The Scientific Section voted that the data based on the results of the pharmacopœial sub-committee on assaying be not printed in the Proceedings. To this I protested and herewith renew my protest, for the following reasons:

1. The Chairman of the Revision Committee authorized me to make such use of the data of the sub-committee on assaying as I desired.

2. I am opposed to concealing any known material facts dealing with chemical problems. It is of course within the experience of all that the truth at times hurts, but it is such hurts that stimulate us to greater activity in eliminating the offenders. It has been my policy at all hearings, legal and otherwise, to plainly set forth the limitation of certain chemical problems, and I have yet to see a case where either chemistry or justice has suffered. Publicity, in my opinion, is the best means of correcting defects and shortcomings. I can only say, with the poet, "Truth crushed to earth will rise again."

3. Some of the members (I recall Drs. Dohme and Lyons) of the sub-committee have published such data of the sub-committee as suited their purpose. I do not believe in such garbled publications. Let the whole become public property. Dr. Dohme (1) published certain results to show why certain methods were introduced into the Pharmacopœia and Dr. Lyons drew on the same data to show what greatly varying results were obtained by the same method in the hands of experimental pharmaceutical chemists. When I called this matter to Dr. Lyons' attention he said: "Yes, but the figures I published do not show such a great variation as some of the data used by you." The figures published by Dr. Lyons show a variation of about 150 per cent. or a variation of about 75 per cent. from an average. It is true the data used by me show a greater variation than the above, but in connection with this I only want to say that when a variation in analytical data exceeds 20 per cent. from an average it might just as well vary 1000 per cent. so far as concerns their practical utility. I cannot fathom the frame of mind of any member of the sub-committee on assaying who is opposed to the publication of any or all of the data obtained in its work and particularly is this true of the members who have themselves published part of such data.

Experience shows that careful analysts can readily come within an upper and a lower percentage variation as indicated below:

2.5 per cent. Atropine, Brucine, Morphine, Strychnine, Cocaine, Nicotine.

5 per cent. Ipecac, Opium, Jalap Root.

10 per cent. Nux Vomica, Coca Leaves, Belladonna Root, Cinchona Bark (total alkaloids), Hydrastis, Stramonium, Guarana, Kola, Cinchona Bark (ether soluble alkaloid), Colchicum, Sanguinaria.

15 per cent. Aconite, both leaves and root, Belladonna leaves, Pilocarpus, Conium, Physostigma.

20 per cent. Henbane.
Table I.—Results of Cooperative Work on Opium, Method I, United States Pharmacopoeia, 1890, with Additions.

Per ct. var... 7.7...

* Based on per cent. of morphine weighed on watch glass.
* Stood twenty-four hours before separating morphine.
* Not included in average, maximum and minimum.
* Results obtained by mixing morphine of both sets of duplicates.
* Acid standardized against morphine.
* Per cent. of morphine by Mallinckrodt's method, 12.92.
* Used porcelain gooch crucible, provided with paper disk, all dried to constant weight.

#### Notes:
- a Not included in maximum, minimum, or average.
- b Dried at 60°.
- c By weight.
- d Temperature during shaking kept below 15° C, and shaking continued ten minutes.
- e Dissolved in acid water, filtered, and water-extracted with ether chloroform = 0.124 per cent.
- f Original weights of alkaloid 2.19 and 2.10 per cent, respectively.
- g Results of titration 1.78 and 1.74 per cent, respectively.
- h Strychnine, by weight, 1.22 per cent.
- i Determined by mixing the drug with slaked lime, moistening with water, drying, and extracting with hot alcohol. This crude alkaloid was purified by solution in acid, washing with ether and shaking out.
- k Strychnine, by British Pharmacopoeia assay, 1.23 per cent.; by weight, 1.26.
- l Cooled to 14° in refrigerator before adding ammonia water. This addition and removal to shake permitted temperature to rise above 15°, but probably not above 20°.
- m Used hematoxylin.
- n Nitric acid did not react well. Not included in maximum, minimum, or average.
- o After cooling to 10° added the ammonia water, then cooled to 6° before shaking, during which time the temperature rose to 16°. Kept it between 14° and 16° by means of a water bath.
- p Used cochineal.
- q Dried at 115° C.
- r Nitric acid reacted well.
- s Temperature was 5°, when shocking.

Mr. Vanderkleed: I think in considering a report like Mr. Kebler's, we are very liable to become our own severest critics, and that it is a mistake to create the impression that pharmaceutical chemists are less accurate in their work, and that the variation in their work is greater than in other lines of assay work. In this connection, I recall a circular gotten out by the proprietors of a certain mineral water which was placed on the market, in which the results of the analyses of a half dozen of the most prominent commercial analytical chemists in the country were placed side by side, and the variations in this water analysis in some instances were very startling. So I do not think we should condemn ourselves absolutely, on the degree of variation brought out in Mr. Kebler's report.

Mr. Eldred: I think Mr. Kebler has perhaps given too much weight to the results showing variations in the assay of drugs—the results of some of that co-operative work, at least. I remember he remarked that the preparation of the sample is one of the very important things. That is true in preparing anything for analysis, whether it be a drug, or iron ore, or whatever it may be; if it is not properly prepared for analysis the results

* Residue purified by re-solution in ether, treatment with water, etc., as in the assay of colchicum corm, U. S. P., not included in average, maximum, or minimum.

† Residue purified as above, substituting petroleum ether for ether, not included in average, maximum, or minimum.
are apt to be very different. Some of the samples which were sent out, presumably ready to be used, were not properly prepared, and the protests which were made against these samples were disregarded by the parties carrying out the co-operative work. I do not know that I can remember off-hand which samples were powdered in various ways, or not, but one sample I remember was powdered so finely that nearly all of it passed through a 150 bolting cloth, by actual experiment; while another sample was so coarsely ground that a very large per cent. of it would not pass through a No. 30 sieve. It is also well recognized that the methods of analysis must be well chosen; that is, not every method will give concordant results even in the hands of people accustomed to doing chemical work. The people co-operating in this work were given no voice at all in the selection of the methods chosen for the co-operative work, and in many cases the methods selected would never have been chosen, I think, if it had been left to the popular vote of the co-operators; and I think many of the variations Mr. Kebler has reported were due to this fact.

The paper was further discussed at some length by Messrs. Lyons, Dohme, C. E. Caspari, Scoville and Puckner, and finally, on motion, duly seconded, referred to the Committee on Publication.

Mr. Dohme then read the paper as follows:

STABILITY OF GALENICAL PREPARATIONS CONTAINING ALKALOIDS.

BY A. R. L. DOHME AND H. ENGELHARDT.

In order to continue our experiments made some time ago on the stability of fluidextracts, etc., containing alkaloids, and confirm, if possible, the results then obtained, the following investigations were made. The samples under examination were taken at random from our control samples of standard staple products manufactured for the pharmaceutical profession. The following results were obtained:

</table>
As will be seen from the above results, all the fluidextracts keep their alkaloidal strength well, with the exception of F. E. coca and F. E. calabar bean. The results obtained with a F. E. coca over two years old are rather surprising (a reduction of 20 per cent. in cocaine strength) as former results have shown that during a period of more than a year, the amount of cocaine is reduced to about one-half, calculating the acid used for neutralizing the basic substance obtained as cocaine. This calculation, however, is only correct when a total destruction of the cocaine molecule takes place and not a partial one, with the formation of ecgonine or other bases. For all the remaining drugs, their fluidextracts keep surprisingly well and the confirmation of our previous experience as published in the "American Druggist" indicates, if it does not prove, that a retail druggist can safely depend upon his leading alkaloid-containing fluidextracts and tinctures if they are properly made and carefully stored and kept.

THE CHAIRMAN: We have another paper on the same subject by Mr. Scoville.

Mr. Scoville here presented his paper, on the subject of "The Permanence of Alkaloidal Fluidextracts and Tinctures."
In January, 1909, a line of experiments was started to ascertain what changes, if any, occur in the alkaloidal fluidextracts and tinctures, when kept under conditions of exposure to light and air similar to the working conditions of a retail pharmacy or laboratory.

Original packages of the preparation were obtained and were stored in a closet having a glass front and in a fairly strong diffused light. The size of the packages was one pint for most of the fluidextracts, a few being obtained in quarts, while the tinctures were obtained in five-pint lots except cinchona (one quart) and hyoscyamus and physostigma, which two were in one gallon size.

As each bottle was opened, one-tenth of its contents was removed and a suitable portion of this used for assay. Assays have been made every three months, and in each case one-tenth of the original volume was removed, thus simulating as nearly as possible the exposure of infrequently-used preparations in the drug-store. In most cases the assay methods were those of the U. S. Pharmacopœia, or the method by which the preparation had been standardized. Each preparation had been standardized when fresh by other assay chemists, so that the first assay in this series served to indicate whether changes had occurred in the sealed containers.

In a few instances, this first assay is lower than later assays—an explanation for these discrepancies is offered under the discussion of results.

The original assays of the preparations of conium, gelsemium and veratrum, in this list, were made by gravimetric processes, while the assays in the series were made by volumetric titration, thus accounting for the lower results on these preparations.

In studying the following table, two things must be kept in mind.

First, that the old preparation is often more difficult to assay than a fresh one, and a modification in the method may be necessary. This was learned early in the work through a statement made by Mr. J. B. Williams, that it was necessary to use alcohol in extracting the alkaloids from old preparations of hyoscyamus, in order to get them all out. It was at first thought that this applied only to preparations of belladonna leaf, hyoscyamus leaf and stramonium leaf, but it was later learned that the same rule applies also to the other mydriatic preparations, to aconite leaf and to coca, though the last is questionable.

This is an important point in the assay of these preparations.

The Pharmacopœia allows the use of alcohol to break emulsions in all assays, hence its use is justifiable. But that alcohol may be necessary for the extraction of the alkaloids, aside from the use for breaking emulsions
is shown in two ways. First, that the addition of alcohol shows an increased extraction of alkaloids by Mayer's test, and second, that the final results by assays with and without alcohol are markedly different, the latter checking closely with the assays on the fresh preparation, while the former are low. This is further explained in the comments on the Mydriatic Drugs, and is also shown in the assays of aconite leaf (4th and 5th assays), wherein the results jump from 0.41 per cent. to 0.50 per cent. through the use of alcohol.

A second point to be borne in mind is that, while other drugs do not require a change in the method for old preparations, yet the extraction of the alkaloids is, in some cases, more difficult and tedious, necessitating a greater number of shakings and the use of a larger amount of solvent. This, in turn, extracts a larger amount of coloring and extraneous matters, and makes titration more difficult (as in ipecac and veratrum), or if gravimetric results are given it is likely to result in increased weight and decreased purity of the alkaloids weighed, as shown in the results on anhalonium.

Sl. ppt. = slight precipitate.  
Vy. sl. ppt. = very slight precipitate.
Aconite.—The assays show no deterioration in any of the preparations. Since, however, the trustworthiness of the chemical assay is questioned by some, Squibb's physiological test has been applied to each. The fluidextract of aconite leaf was originally standardized by physiological test, and found to respond at a dilution of 1 to 350. It responded at the same dilution in February, 1910. The fluidextract of the root was not standardized physiologically when fresh, but it now responds to the test at a dilution of 1 to 800, which is satisfactory for a fresh preparation.

Likewise the tincture, not standardized by this test when fresh, now responds at a dilution of 1 to 90, corresponding to 1 to 900 in the drug.

The extract was standardized at 1 to 3000, and now responds to the same dilution.

All of the physiological tests were checked by two other chemists, and only the results in which all three agreed are given.

So neither by chemical nor by physiological test is there any deterioration shown.

Anhalonium.—This is a gravimetric assay, and the residue is so deeply colored that titration is impracticable. The apparent increase in strength may easily be due to a larger amount of impurities in the later assays. The assay of this preparation is unsatisfactory at best.

The Mydriatic Drugs—Belladonna, Hyoscyamus, Scopola and Stramonium.—There is a marked peculiarity in the assay of these preparations, in that the older preparations yield their alkaloids much more difficulty than the fresh. This is particularly true of the leaf preparations in which the coloring matters and extractive are in excess. I have found it impossible to extract all of the alkaloids from these aged preparations by a strict following of the U. S. P. assay process.

The U. S. P. allows of the addition of a little alcohol to break emulsions which may have formed in shaking, but with these preparations the addition of alcohol is necessary, not merely to break probable emulsions, but to extract the alkaloids.

This was first called to my attention by Mr. Williams, who stated that in the first shaking out of the alkaloids (the fluidextract, rendered alkaline with ammonia, being shaken out with successive portions of chloroform) the chloroform solution soon ceases to show the presence of alkaloids. If now 5 to 10 Cc. of alcohol be added to the alkaline solution, and again shaken with a fresh portion of chloroform, a few drops of the chloroformic solution, after evaporation, will show marked quantities of alkaloid to be present, by the Mayer's test. I have found this to be true of all the mydriatic preparations.

The discrepancies in the figures for scopola are explained in this way: In the first three assays no emulsion formed and no alcohol was used. In the fourth assay alcohol was used to break an emulsion (in the first extraction), and the result is higher. I do not find any evidence of a
decomposition of the alkaloids in these assays when alcohol is used to favor extraction, and there is a fair agreement between the gravimetric and the volumetric results on these drugs.

In scopola the following shows this:

<table>
<thead>
<tr>
<th></th>
<th>1st Assay</th>
<th>2nd Assay</th>
<th>3rd Assay</th>
<th>4th Assay</th>
</tr>
</thead>
<tbody>
<tr>

<td>0.26</td>
<td>0.268</td>
<td>0.304</td>
<td>0.297</td>
</tr>
</tbody>
</table>

Similar figures can be supplied for the other preparations.

Hyoscyamus is particularly hard to extract, the last assay requiring 15 to 20 separate extractions with chloroform in order to get out all of the alkaloid. The subsequent extraction of the chloroformic solution with acid, then again of this solution with chloroform, are also tedious. In my judgment this increased difficulty of extraction accounts for the reported deteriorations of fluidextract of henbane which have been made. I do not find evidence of any real deterioration of any of these drug preparations, but that some change in constitution occurs, which is not a deterioration, I do not doubt.

Cinchona.—Only two of the cinchona preparations show any marked deterioration.

It will be noticed that the fluidextract of cinchona, U. S. P., sample A, was about 19 months old when first opened. It then dropped from 4 per cent. to 3.3 per cent. of ether-soluble alkaloids, and subsequent assays show a steady deterioration.

When the last assay was made, the heavy, gelatinous precipitate which had formed was broken up, and found to weigh (after being well drained) about 75 Gm. A portion of this was assayed and found to contain 4.84 per cent. of ether-soluble alkaloids. In this instance the precipitate has carried down a considerable portion of the alkaloids. Sample B (date of manufacture unknown), which had stood in the same case without disturbance two years, assayed:

January 16, 1908 ................................ 3.97 per cent.
December 5, 1908 ................................ 3.71 per cent.
February 4, 1910 .................................. 3.71 per cent.

This sample is still clear and without precipitate.

The U. S. P. tincture of cinchona also shows a deterioration and a considerable precipitate, while the other preparations show little or no change in strength and slight, if any, precipitation. It seems to be fair to infer that in the cinchona preparations a marked precipitation indicates a dete-
rioration in alkaloidal strength. So long as they remain clear, or nearly so, there is no change in strength.

_Coca._—Without doubt fluidextract of coca deteriorates rapidly. The apparent increase shown in the figures does not look as well when one compares the gravimetric with the volumetric figures.

</table>

In these assays the amount of ether used, both for the first and second extraction, was exactly the same in each assay, no attention being paid to the Mayer test.

The fluidextracts were also assayed by the Squibb process, using refined petroleum ether for the first extraction in order to eliminate all alkaloids except cocaine. The fluidextract of coca yielded by this method 0.317 per cent. gravimetric, 0.310 per cent. volumetric. The miscible fluid-extract assayed 0.44 per cent. gravimetric, 0.15 per cent. volumetric. The petroleum ether process is more satisfactory as an assay process, since it allows of extraction until no test is obtained with Mayer's solution, and it extracts only cocaine.

As confirming the deterioration of this preparation, three fluidextracts were made in July, 1908, using different menstrua, and were assayed by the petroleum ether process. When fresh these assayed 0.474, 0.468, 0.483 per cent. respectively. After a year and a half they assayed by the same process 0.238, 0.258, 0.333 respectively.

_Colchicum._—These preparations were assayed by a modification of the Gordin-Prescott method, which has been accepted by the drug laboratory of the United States Department of Agriculture as giving more accurate as well as more uniform results than the U. S. P. method. The results are lower than the U. S. P. assay, but there is less danger of weighing fatty matters as alkaloid. Even this method is not altogether satisfactory, and allowance should be made for impurities, as in any gravimetric process.

Under the conditions I do not feel warranted in concluding that there is any change in these preparations, since slight changes in the process are likely to cause changes in the results, and the purity of the alkaloids as weighed is questionable.

_Conium._—These preparations were assayed volumetrically in order to avoid the errors of gravimetric results. All the figures given, except the standardized assay, are volumetric results. The preparation becomes harder to extract as it grows older, and the last assays were tedious. Here again imperfect extraction of the alkaloid may easily account for reported deterioration of conium preparations. I do not consider that such conclusion is warranted when the added difficulties of extraction are considered.
**Gelsemium.**—The substitution of volumetric for gravimetric assay may account for the results being all lower than the standard. But the gravimetric results in the series (both being recorded) are also slightly lower in most cases. The differences are not very great, and the uniformity of results in the volumetric series seems to indicate stability in these preparations.

**Hydrastis.**—The tincture shows a slight but distinctly crystalline precipitate, likewise the aqueous fluidextract. Since hydrastis preparations are known to deposit hydrastine readily, conditions may have much to do with their permanency.

The old preparations are no more difficult of assay than the new, and the final alkaloidal residue has but little color. If any change in these preparations occurs, which seems improbable, it is more likely to be due to a deposition of alkaloid than to any change in its character.

**Ipecac.**—When 10 Cc. of fluidextract is used for assay, as directed by the Pharmacopoeia, so much coloring matter is extracted that the titration becomes very difficult. Furthermore, the older preparations require an increased number of extractions, and this results in a larger proportion of the coloring matter in the final residue. Hence more care is necessary in assaying old than for new preparations.

The results do not show any material change in these.

**Pilocarpus.**—Shows a deterioration, and it is interesting to note that it has also precipitated markedly. Here again the question whether deterioration and precipitation go together may be raised.

**Sanguinaria.**—Undoubtedly undergoes a change in its alkaloids in all its preparations. The alkaloids obtained from a fresh preparation by ether are white, but after six months it is impossible to obtain a white alkaloid. The ether solutions have a deep red to violet tint, and the final residue is deeply colored. By using strong acids (10 per cent. nitric or 60 per cent. phosphoric acid), and a large number of shakings, a residue can be obtained approximating the amount in the fresh preparation, but it will be very dark in color and mostly amorphous.

The official (acetic) fluidextract appears to change more rapidly than the hydroalcoholic.

**Veratrum.**—This is another instance of a volumetric assay being substituted for a gravimetric. The alkaloids of veratrum do not respond sharply to cochineal in titration, and the vagaries in the results may well be ascribed to this fact.

The gravimetric assays agree fairly well with the original standard in all cases except the last assays, which are high for both the fluidextract and the tincture. Considering the unsatisfactory end-point in titration, and the reasonable uniformity of results in the gravimetric results, it may safely be concluded that no change is shown in these preparations.
SUMMARY.

Of the sixty preparations, the oldest is now three and one-quarter years, and the majority are between one and two years old.

Each (except the solid extracts) has been opened at least five times within the past year, and a portion taken out.

Old preparations of the mydriatic drugs are much more difficult to assay than fresh preparations, particularly the leaf preparations, and require the use of alcohol during the process of extracting the alkaloids.

Coca and sanguinaria preparations show a rapid deterioration, and a change in composition.

The cinchona preparations deteriorated, accompanied by and apparently caused by a marked precipitation. A corresponding preparation which has remained clear and been less exposed, shows no deterioration.

Pilocarpus fluidextract shows a slight deterioration, and also a marked precipitation.

Colchicum and conium show vagaries in assay results which forbid positive conclusions, but at least a fair degree of permanence is indicated.

Gelsemium and hydrastis show a possible slight loss in strength, but not sufficient to be of serious import.

The other preparations all show a stability under varying conditions of exposure, etc., which is entirely satisfactory.

THE CHAIRMAN: We have another paper along the same line, which was inadvertently placed in the program for this afternoon's session. It is entitled "The Rate of Deterioration of Fluidextract of Ergot," by Dr. Horatio C. Wood, Jr. If there is no objection I would like to have it presented along with these other two.

Dr. Wood here read his paper.

THE RATE OF DETERIORATION OF FLUIDEXTRACT OF ERGOT.

BY HORATIO C. WOOD, JR., M. D.

The two drugs of whose quality there has been the greatest complaint in recent years are without doubt digitalis and ergot. In the case of digitalis it has been shown by several observers that one of the important causes of its variability is the deterioration which takes place in the galenical preparations after their manufacture. Thus Houghton (Pharm. Journ., October 23, 1909) found that the fluidextract of digitalis lost on an average of 10 per cent. a year and the tincture 9 per cent. Focke (Pharm. Zeitung, volume 49) found that if protected from the light the loss in tincture of digitalis ranged from 10 to 17 per cent. a year, while if exposed to the light it might reach as high as 33 to 50 per cent. In connection with the wide differences in the activity of the different samples of fluidextract, it is interesting to note that while the range in activity of crude digitalis was within the limit of less than 200 per cent., there was a variation in the fluidextract of 400 per cent., which is very suggestive.
that one of the most important reasons for the poor quality of so much tincture of digitalis is the changes taking place after its manufacture. It has seemed of interest to me to determine whether this same factor holds true in the case of ergot.

I have, in conjunction with Dr. Hofer in the last two years made comparative tests of a large number of different samples of fluidextract of ergot, both physiologically and chemically. As the methods employed have been already published I shall not go into detail concerning these, but simply state that for physiological assay the figures given represent the rise in the blood pressure in a dog. The chemical assay is based upon the percentage of sphacelotoxin, which as I have shown (American Journal Pharm., May, 1909) corresponds accurately to physiological tests. I would call attention to the fact that although the physiological and chemical figures bear a constant relation to each other, yet the physiological activity does not increase as rapidly as the per cent. of sphacelotoxin, so that when we come to calculate the comparative activity of two samples on a percentage basis, the figures given by the chemical and physiological tests will not be absolutely equal although more or less harmonious.

My attention was first called to the rapidity with which fluidextract of ergot diminishes in power in connection with the sample I have labeled No. 1. Of this preparation I received from the manufacturer a quart bottle from which I was making physiological tests every few days, and was somewhat at a loss to explain the differences in strength in some tests which were made after I had had the bottle for several weeks. In such a short space of time as three months, this sample, which when fresh, had given an average rise of 47, had fallen to 19. This difference in strength was so extraordinary that I determined to make a more careful series of observations as to the rapidity with which the fluidextract of ergot deteriorated under various conditions of keeping. My early experience in this investigation led me to believe that the most important factor in the deterioration of fluidextract of ergot was the action of the air and I have therefore adopted three series of conditions; first, the fluidextract was kept in a bottle stoppered only with a piece of cotton to keep out the dust, admitting free contact with the air, alcohol being added from time to time to make up for the loss through evaporation; second, in bottles which were completely filled and closed with well-fitting corks; and third, in bottles which were completely filled so as to exclude all air and tightly stoppered and sealed with shellac. In the last instance the bottles employed were either kept in the dark or were deep amber color; in the others some of the bottles were amber and some were plain.

The greatest deterioration observed in any of the open bottles was in No. 7, which, when fresh, have a rise of 34 physiologically and 0.70 per cent. of sphacelotoxin, six weeks later gave only rise of 18 and a sphacelotoxin content of 0.39, a deterioration of about 30 per cent. a month.
The slowest loss of power in this series was with No. 2, which gave a loss in physiological power of 15 per cent. a month, and according to the chemical assay, of approximately 11 per cent. a month.

With the bottles which were corked, the deterioration ranged from 4 to 15 per cent. a month, and in the case of the sealed bottles the loss was very distinctly less, in one instance being less than 1 per cent. a month, in no case over 9 per cent. a month. The longest periods of observation were a few weeks less than a year. Sample No. 2, which when fresh gave a rise in blood pressure of 63 mm, 11 months later a rise of 36, showing a loss of 43 per cent. in 11 months or a little less than 4 per cent. a month; No. 4 in 11½ months fell from 37 to 17 in its physiological activity, a loss of 4.7 per cent. a month.

The loss of strength does not seem to progress at a constant rate, but is most rapid immediately after the manufacture of the preparation. For instance, in the case of No. 2 which was obtained from the manufacturer within two weeks of its completion we obtained a rise of 63 mm. in the blood pressure; 5½ months later a rise of 39, showing a deterioration amounting to 6.9 per cent. a month. 11 months later this preparation produced a rise of 36 mm., so that in the last six months the loss in potency was only ¾ as rapid as in the previous six months. In the case of No. 4 the loss during the first four months was at the rate of 5.4 per cent. a month and in the next seven months at the rate of 4.3 per cent. of the original strength per month. It is, however, manifestly not fair to calculate the percentage loss in different periods on the base of the original strength, for instance in sample No. 2 the rise in pressure at eleven months was only 3 mm. less than that at 5½ months. This 3 mm. would be approximately 5 per cent. of the original 63 but is nearly 8 per cent. of the 39 mm. which was the rise at the sixth month and if we wish to calculate the rate of loss in the later months, the figure for the calculated percentage must evidently be the figure of the last observation so that while the sample showed a loss of 0.5 per cent. a month, if we calculate on the original base of the strength at the fifth month, it should be 1.4 per cent.

But even allowing for this difference in the method of calculating the percentage loss, we find that there is a retardation of the deterioration the longer the preparation is kept. Thus in the sealed bottle No. 5 showed an original sphacelotoxin content of 0.95 and three months later of 0.70, a deterioration of 8.8 per cent. a month. In the next seven months it fell to 0.56, a deterioration from the 0.70 at the rate of 2.9 per cent. a month.

While my experiments upon the subject are not numerous enough to lead to positive conclusions, such evidence as I possess leads me to believe that the fluidextract of ergot deteriorates more rapidly than the crude powdered drug. I have really only one satisfactory series bearing upon this point and that is the sample labeled No. 1. This fluidextract was received from the manufacturer along with the sample of the powdered
drug from which the fluidextract was made. At the time it was received I had not yet worked out the method of chemical assay and therefore cannot give the figure of sphacelotoxin content, but 3½ months later it showed 0.48 per cent. From the powdered ergot which was received at the same time there was made six months later by Professor Cook, a fluid extract and this showed .93 per cent.

To sum up my results, I would say that under the most favorable conditions fluidextract of ergot loses in the first year after its manufacture between 45 and 50 per cent. of its physiological power and that under unfavorable conditions, as when imperfectly protected against atmospheric influences, the loss is much greater than this and may amount to more than 50 per cent. in three months. It seems to me therefore essential that all preparations of ergot should be marked with the date of their manufacture on the label, as is done in the case of antitoxin.

Average .......... 7.1 months 4.4 per cent. 4.4 per cent.

The Chairman: The subject is now open for discussion.
Mr. Eldred: I am sorry I am not a physiologist, and I may be caught in some error if I attempt to talk along this line, so I hope you will excuse any errors I may make. I would like to ask Dr. Wood if those rises in blood pressure which he reports are the initial rises, or rises after a certain period of time.

Dr. Wood: I may say, gentlemen, that in conjunction with Dr. Hofer, I published a preliminary communication on this subject last February a year ago, in which we took the rise at the end of five minutes. Since that time, however, we have modified our method slightly and do not take the initial rise, nor the rise in five minutes, nor the rise in ten minutes, but take the average of the three as showing the rise which was maintained for ten minutes.

Mr. Eldred: I would also like to know what his experience has been as to the initial rise, and the rise, say, after ten minutes; which is the more uniform—if he were to take either of those, which would he consider the most reliable as determining the value of the ergot?

Dr. Wood: If I had to take but one, I would take the ten-minute rise.

Mr. Eldred: As I say, I am not competent to speak on this subject; all the information I have upon it has been acquired by talking with our physiologist, and that was his opinion that it was necessary to consider both the initial rise and the later, and in using that method he has found results that are absolutely opposite to what Dr. Wood reports in regard to the deterioration of fluidextract of ergot. In other words, operating on some samples of fluidextract which we happened to have in the laboratory, he found that those were almost as active as fresh samples, the variation being only such as could have been considered as within an experimental area. Of course we did not know what was the strength of these old fluidextracts when they were made, because we had not the method of testing them, but we do know that these fluidextracts, four years old to-day, are as active as fresh extract of ergot.

Mr. Lyons: These papers are very interesting, and very useful in the line of investigation. Mr. Scoville reported an examination of extract of cinchona, and apparent deterioration of the fluidextract. My own examination of ipecac showed the same thing—not the official extract, but one of the solubles. I had examined it several times, at intervals of three months, finding a deterioration in the fluid, but suspected that there was a deposit which was bound to be there, and that I found to be true. I have found, as others have found, deterioration progressing very rapidly.

Dr. Wood: Might I be permitted just a word in reply to Mr. Eldred? In the first place, I want to say that taking an old fluidextract of ergot and testing it is absolutely no evidence whether it has deteriorated or not. Unless you know the original strength of that ergot, the age of it is no criterion.

Mr. Eldred: I would just like to say that we had a very definite basis for our start on this extract of ergot. As I stated, four years ago we had no idea of assaying ergot by a rise in blood pressure, but for the last two years we have examined an enormous number of samples of fresh ergot, and ergot of all ages. We have also tested by this method a large number of lots of fluidextract of ergot, as soon as they were made, and my statement was that these old fluidextracts (two of them four years old at the present time) had as great an effect on the blood pressure as the average fresh fluidextract made from samples of ergot that we knew to represent as good ergot as could be purchased on the market.
The Chairman: We have before us now, several papers dealing more particularly with laboratory work. These are by Mr. H. J. Goeckel. One is entitled "The Result of a Few Drug Assays"; another is "The Result of Eighty-seven Opium Assays"; and the third, "The Result of Sixty Coca Assays." Unless Mr. Goeckel is present, we will read them simply by title, and pass on to the next paper, which is by Mr. Eldred on the subject "Analytical Data obtained in the Examination of Official Substances."

Mr. Frank R. Eldred here presented his paper, in abstract.

SOME DATA OBTAINED IN THE EXAMINATION OF OFFICIAL SUBSTANCES.

FRANK R. ELDRED.

The only excuse for presenting a paper of this character, which contains no new facts, and which goes over ground already covered by many workers, is the desire to make as many data as possible available to the pharmacopœial revision committee. It has been considered in most cases unnecessary to comment upon the data presented, but a few general comments may not be out of place.

Melting Point.—Considering the ease with which this constant can be determined, it is one of the most valuable aids in determining the identity and purity of many organic substances. However, unless it is carefully determined in a proper manner, the results vary so much that it loses much of its value. The looseness with which melting points are stated in the literature is well known; it is usually not even stated whether or not the melting point has been corrected for steam exposure. If melting points are not so corrected it becomes a very important matter that the determinations be made in a uniform manner, otherwise the results will not be comparable. The pharmacopœia should prescribe a standard form of apparatus and detailed directions for making this determination. None of the many special forms of apparatus devised for this purpose should be used, first because they are unnecessary, but chiefly because none of them are in general use and the apparatus selected should be that in which most of the published melting points have been determined. The author would recommend the form of apparatus described by Mulliken ("A Method for the Identification of Pure Organic Compounds," vol. 1, p. 218, et seq.). All melting points in this paper are uncorrected and have been determined in an apparatus of this kind in the manner described by Mulliken. If the pharmacopœial melting points are to be of value as criteria of purity a variation between certain limits should be allowed; it is of no value to state the melting point of the chemically pure substance when it is neither possible nor desirable to use this medicinally. In some cases such limits, usually too narrow, are given in the pharmacopœia, in other cases a definite melting point even to a fraction of a degree is stated. The inconsistency of this is seen when it is remembered that every operator is left free to choose his own method, and that different methods of determina-
tion may cause a difference of several degrees in the observed melting point. Definite forms of apparatus and methods of observation should also be adopted for determining melting points which cannot be determined by the ordinary capillary tube method. These methods should include the determination of the congealing point of substances liquid at ordinary temperatures, the titer point of fatty acids, and the melting points of solid fats and waxes, although the melting points of some of the waxes can be satisfactorily determined by the ordinary capillary tube method. For the determination of the congealing point the apparatus and method described by Gildemeister & Hoffman ("The Volatile Oils," translation by Edw. Kremers, p. 188) are entirely satisfactory. The Association of Official Agricultural Chemists have official methods for the determination of the titer point and the melting point of fats, but for the latter determination a simpler method, for instance the hydrostatic method, using a capillary open at both ends and immersed in water, would probably be preferable.

Boiling Point.—When this determination is necessary it is also important that a uniform method be followed, the methods described by Mulliken (ibid., p. 221-223) might be used.

Specific Gravity.—Most of the specific gravity determinations reported in the literature have been made at 15°/15° C., and as it is almost as easy to make the determinations at this temperature as at 25°/25° C., it seems unfortunate that the pharmacopoeia has adopted the latter temperature.

Refractive Index.—This constant is of value in the examination of many oils and other substances. Tables giving the refractive indices corresponding to different strengths of various pharmacopoeial articles would be very useful.

Atomic Weights.—The Pharmacopoeia should certainly adopt the international oxygen standard.

The data which follow are in most cases from determinations made during the last two or three years.

Acetanilide.—The melting-points of thirty-eight lots examined during the last three years varied from 112.5° to 113.5° C. A sample which melted at 112.5° C. was recrystallized several times from alcohol and then melted at 115° C. The melting-point of acetanilide is variously stated as 113° C. to 120° C. As it seems to be impossible to obtain acetanilide commercially which melts much above 113° C., the limiting temperatures might be made 113° C. and 116° C.

Acetone.—The specific gravity at 15°/15° C. has been found to vary from 0.797 to 0.801. Most lots distilled completely between 56° C. and 57° C., and met the official requirements in regard to residue and behavior with potassium permanganate; in one lot, however, purchased for reagent purposes, the permanganate color lasted only seven minutes. Most lots are slightly acid to phenolphthalein, requiring from 8 Mg. to 13 Mg. of sodium hydroxide per liter for neutralization.
Acetphenetidin.—The melting-points of fifteen lots varied from 133° C. to 134.5° C., but one lot examined had a melting-point of only 131° C. Twenty-four lots of Bayer & Co.'s phenacetin had melting-points varying from 131° C. to 135° C. Most of the lots from all of the manufacturers represented melted between 133° C. and 134° C., and only one lot melted at 135° C. As 135° C. is probably the melting-point of pure acetphenetidin, a variation in melting-point from 133° C. to 135° C. should be allowable.

Boric Acid.—As glycerin is usually acid, even though the acidity cannot be detected by litmus paper, this fact should be taken into consideration in the titration of boric acid, otherwise it will occasion an error probably amounting to from 0.1 per cent. to 0.4 per cent. The phenolphthalein should be added to the water and glycerin and the solution neutralized before adding the boric acid. A solution weaker than normal should be used in the titration if an accurate determination is required. When titrated in the above manner fourteen lots have been found to vary from 98.4 per cent. to 99.8 per cent., only three lots giving the latter figure.

Citric Acid.—Citric acid should contain 8.6 per cent. of water of crystallization; when powdered it often contains less than this amount, sometimes as low as 6 per cent.; this will cause trouble in the preparation of the official effervescing salts.

Phosphoric Acid.—Some sold as 85 per cent. contains as much as 89 per cent. of phosphoric acid. When much stronger than 85 per cent. it sometimes crystallizes and is rather troublesome to liquefy.

Acetic Ether.—Eleven lots have been found to vary from 89 per cent. to 96 per cent. Care should be taken to use acetic ether which has been washed with water for saturating the water to be used in this determination, otherwise low results will be obtained.

Aloes.—Twenty-four lots of crude aloes yielded from 0.5 per cent. to 9.7 per cent. of ash, the yield of ash was in most cases between 1 per cent. and 4 per cent.

Thirty-six lots of powdered aloes yielded from 1.4 per cent. to 4 per cent. of ash. The ash was below 3 per cent. in all except three lots.

Althaea.—Twelve lots of powdered althaea yielded from 4.9 to 7.3 per cent. of ash.

Antipyrine.—The melting points of ten lots were found to vary from 109° C. to 110° C. Judging from these figures and those reported by other chemists, the melting point of 113° C. as given in the U. S. P. and in many of the standard works on chemistry, is too high. A melting point of 109° C. to 111° C. would probably be acceptable.

Asafetida.—Thirty-nine lots of powdered asafetida yielded from 16 per cent. to 64 per cent. of ash, and from 18 per cent. to 61 per cent. of alcohol-soluble material. Crude asafetida varies so much and is so difficult to sample that it seems hardly worth while to present any data in regard to it. At times it is very difficult to obtain any which has a large
enough amount of alcohol-soluble material to meet the official requirement. Twenty lots containing 50 per cent. or more of alcohol-soluble material yielded from 6 per cent. to 30 per cent. of ash, nine of these lots yielded more than 19 per cent. of ash.

Atropine.—Five lots melted between 114.5° C. and 115.5° C. and only one lot had a melting point as low as 114° C.

Atropine Sulphate.—The melting point is influenced by the rate of heating. Twenty lots examined had melting points from 186° C. to 191° C.

Belladonna Leaves.—Twenty-six lots assayed during 1908 were found to contain from 0.23 per cent. to 0.62 per cent. of alkaloids. Only three of these lots assayed less than the official standard of 0.3 per cent. while fourteen lots assayed more than 0.4 per cent. The average content of alkaloids in all lots assayed was 0.409 per cent.

During 1909 twenty-three lots were assayed, the results varying from 0.18 per cent. to 0.54 per cent; thirteen of these lots were above 0.4 per cent. and only two below 0.3 per cent. The average for 1909 was 0.407 per cent. alkaloids.

Belladonna Root.—During 1908 only six lots were assayed, three of which were below the official standard. The minimum result was 0.18 per cent. and the maximum 0.52 per cent.

Benzoin.—Forty-four lots contained from 9 per cent. to 35 per cent. of material insoluble in alcohol, 19.1 per cent. being the average. Seventeen of the lots contained more than 19 per cent. of material insoluble in alcohol. The yield of ash was in most cases not above 2 per cent.

Benzosulphinide.—The melting points of twenty lots of saccharin examined varied from 217° C. to 220.5° C. Three lots melted at 217° C., four lots at 218° C., eleven lots at 219° C., one at 220° C. and one at 220.5° C.

Betanaphthol.—Ten lots had melting points from 121° C. to 122° C.

Bismuth Subcarbonate.—Sixteen lots yielded on ignition from 91 per cent. to 91.5 per cent. of bismuth oxide.

Bismuth Subgallate.—Twenty-four lots yielded on ignition from 51.8 per cent. to 53.6 per cent. of bismuth oxide; one lot yielded 55.7 per cent., and one only 51 per cent.

Bismuth Subnitrate.—Thirty-six lots yielded amounts of bismuth oxide varying from 79.7 per cent. to 80.6 per cent. One lot yielded 86 per cent. of bismuth oxide, and one only 77 per cent.

Bismuth Subsalicylate.—In five lots examined the yield of bismuth oxide varied from 62.6 per cent. to 66.5 per cent.

Monobromated Camphor.—Twenty-five lots had melting points varying from 74° C. to 76° C.

Capsicum.—Forty-eight lots yielded from 11 per cent. to 26 per cent.
of ether-soluble oleoresin (dried for 1 hour on a water-bath), the average being 18 per cent. Six lots were below 15 per cent.

Cocaine Hydrochloride.—The melting-point is of no value unless the sample is heated rapidly at a definite rate. A sample heated rapidly to 175° C., and then at the rate of 6° C. per minute melted at 191° C.; the same sample heated rapidly to 170° C., and then at the rate of 2° C. per minute melted at 189° C.; when heated slowly it melted at 180° C.

Cochineal.—The yields of ash from five lots of black grain were from 5.0 per cent. to 8.2 per cent.; from four lots of silver grain, 23.3 per cent. to 25.5 per cent.

Codeine.—Fifteen lots of crystallized codeine had melting-points from 152° C. to 154° C. One lot, heated to expel the water of crystallization, melted at 155° C.

Eucalyptol.—There is no difficulty in obtaining eucalyptol optically inactive, melting between 1° C. and 2° C., and having a specific gravity at 15°/15° C. of 0.926 to 0.930. In examining twenty-six lots three were found to be optically active from —1° C. to +2.40° C.; one lot melted at —2° C., one at —0.5° C. and two at 0° C. The melting-point should certainly not be lower than 0° C., and probably 1° C. to 2° C. would be a satisfactory requirement.

Glycerin.—The strength of glycerin is much more conveniently determined by the refractive index than by the specific gravity. The determination of acidity by titration with weak standard alkali, using phenolphthalein as indicator, affords useful information in regard to quality.

Glycyrrhiza.—In examining a large number of lots of powdered licorice root the yield of ash was found to be from 4 per cent. to 7.5 per cent. The powdered extract was found to yield about the same amount of ash.

Guaiacol Carbonate.—Three lots melted between 84° C. and 85.5° C.

Guaiac.—Twenty-seven lots of crude guaiac resin yielded from 0.2 per cent. to 4 per cent. of ash, and from 67 per cent. to 99 per cent. of alcohol-soluble material, only five lots contained more than 15 per cent. of material insoluble in alcohol.

Twenty lots of powdered guaiac resin yielded from 1 per cent. to 30 per cent. of ash, only five lots yielded more than 5 per cent. The amount of alcohol-soluble material varied from 54 per cent. to 95 per cent., only four lots being above 85 per cent.

Mercuric Chloride.—Forty-four lots varied from almost complete solubility in water to 1.1 per cent. insoluble residue. The residue insoluble in water exceeded the official limit in only four lots.

Hydrastis.—Nineteen lots were assayed during 1908, the average hydrastine content being 3.3 per cent. The lots varied from 2.8 per cent. to 3.8 per cent.

During 1909 twenty lots were assayed, the average being 3.6 per cent.: the lowest assay was 2.8 per cent., and the highest 4.9 per cent.
**Data Obtained in the Examination of Official Substances.**

_Hyoscyamus._—Seven lots assayed during 1908 varied from 0.042 per cent. to 0.109 per cent. of alkaloids, the average was 0.075 per cent. Four lots were below the official requirement.

During 1909 fifteen lots were assayed, the lowest result being 0.039 per cent., the highest 0.14 per cent., and the average 0.085 per cent. Seven lots were below the official requirement.

During the present year two lots have been assayed which contained only 0.02 per cent. of alkaloids.

_Iodine._—A large number of lots examined contained from 98.3 per cent. to 99.9 per cent. of iodine.

_Solution of Formaldehyde._—One hundred lots were found to contain from 36 per cent. to 39 per cent. of formaldehyde; most of the lots were above the official requirement.

_Lupulin._—Twenty-six lots were examined and only one was found to contain less than 60 per cent. of ether-soluble material; this sample contained 42 per cent. of ether-soluble material and yielded 36 per cent. of ash. The other lots varied from 64 per cent. to 76 per cent. of ether soluble material and yielded from 10.8 per cent. to 20.8 per cent. of ash. Four lots otherwise satisfactory yielded over 18 per cent. of ash and nine lots over 15 per cent. The ash limit should be raised to 18 per cent. and a good drug could be insured by raising the requirement for ether-soluble material to 65 per cent. or 66 per cent.

_Lycopodium._—Four lots yielded from 1.1 per cent. to 2.2 per cent. of ash. The official ash limit is unnecessarily high.

_Mastic._—The acid values of fourteen lots varied from 50 to 67, only one lot being as high as the official requirement of 65.

_Methylene Blue._—Much of the methylene blue on the market yields an amount of ash in excess of the official limit of 0.4 per cent.; thirty-two lots have been found to yield from 0.04 per cent. to 25.0 per cent. of ash. The ash limit could be raised to 1 per cent. if zinc and arsenic are excluded by suitable tests. A limit of material insoluble in alcohol, and a method of colorimetric valuation or titration with titanous chloride would be of value in insuring a satisfactory product.

_Myrrh._—Twenty lots of crude myrrh averaged about 58 per cent. of material insoluble in alcohol, and about 32 per cent. of alcohol-soluble material (dried for one hour on a water bath); this leaves about 10 per cent. of material volatilizing under these conditions. The largest residue insoluble in alcohol was 74 per cent., the smallest 52 per cent. The ash averaged 8 per cent., the lower and upper limits being 4 per cent. and 14 per cent. Eleven lots of powdered myrrh varied from 29 per cent. to 53 per cent. of alcohol-soluble material, the average being about 35 per cent. The ash averaged about 11 per cent, and varied from 5 per cent. to 16 per cent.

_Nux Vomica._—Two lots assayed in 1908 contained 1.42 per cent. and 1.43 per cent. of strychnine.
Eight lots in 1909 averaged 1.42 cent. and varied from 1.27 per cent. to 1.58 per cent.

Oil of Bitter Almond.—Eleven lots contained from 2 per cent. to 3.8 per cent. of hydrocyanic acid.

Expressed Oil of Almond.—Eight lots were examined with the following results:

\[
\begin{align*}
\delta_{15^\circ/15^\circ} & = 0.917 \text{ to } 0.919 \\
\alpha_D & = 1.4703 \text{ to } 1.4705 \\
\text{Iodine value (Wijs)} & = 93.4 \text{ to } 100.0 \\
\text{Saponification value} & = 188.5 \text{ to } 193.0
\end{align*}
\]

Oil of Anise (Star).—Fifty-one lots varied in optical rotation from \(+0.17^\circ\) to \(-3.5^\circ\), and in the congealing point from \(14.5^\circ\) to \(18^\circ\).

Oil of Caraway.—Nineteen lots varied in optical rotation and specific gravity within the following limits:

\[
\begin{align*}
\delta_{15^\circ/15^\circ} & = 0.904 \text{ to } 0.912 \\
\alpha_D & = +76.1^\circ \text{ to } +80.3^\circ
\end{align*}
\]

Oil of Coriander.—Fifteen lots were found to vary within the following limits:

\[
\begin{align*}
\delta_{15^\circ/15^\circ} & = 0.866 \text{ to } 0.912 \\
\alpha_D & = +9.9^\circ \text{ to } +11.7^\circ
\end{align*}
\]

Oil of Erigeron.—Eight lots varied within the following limits:

\[
\begin{align*}
\delta_{15^\circ/15^\circ} & = 0.869 \text{ to } 0.883 \\
\alpha_D & = +53.6^\circ \text{ to } +63.6^\circ
\end{align*}
\]

Oil of Fennel.—Six lots examined were found to vary within the following limits:

\[
\begin{align*}
\delta_{15^\circ/15^\circ} & = 0.964 \text{ to } 0.975 \\
\alpha_D & = +13.3^\circ \text{ to } +17.1^\circ \\
\text{Congealing point} & = 3^\circ \text{ to } 5^\circ
\end{align*}
\]

Oil of Hedeoma.—Fourteen lots were examined with the following results:

\[
\begin{align*}
\delta_{15^\circ/15^\circ} & = 0.926 \text{ to } 0.932 \\
\alpha_D & = +18^\circ \text{ to } +31^\circ
\end{align*}
\]

Soluble in from 1.5 to 3.5 volumes of 70 per cent. (by volume) alcohol.

Oil of Lavender Flowers.—Thirteen lots were examined with the following results:

\[
\begin{align*}
\delta_{15^\circ/15^\circ} & = 0.886 \text{ to } 0.903 \\
\alpha_D & = -3^\circ \text{ to } -6.7^\circ \\
\text{Ester number} & = 90 \text{ to } 98
\end{align*}
\]

Soluble in 2 to 3 volumes of 70 per cent. (by volume) alcohol.
Linseed Oil.—The following data were determined in examining twenty-seven lots:

\[ d_{15^\circ}/15^\circ \] ............... 0.932 to 0.934
\[ aD \] 20\(^\circ \] ...................................... 1.4000 to 1.4815
Iodine value (Wijs) ............... 171.0 to 200.0
Saponification value ............... 187.5 to 196.8

Oil of Peppermint.—Forty-two lots were examined with the following results:

\[ d_{15^\circ}/15^\circ \] ............... 0.900 to 0.909
\[ aD \] ........................................... -19.4\(^\circ \) to -28.8\(^\circ \)
Menthyl acetate ............... 5.3\% to 13.1\%
Total menthol ............... 50.0\% to 66.0\%
Soluble in from 2 to 4 volumes of 70 per cent. (by volume) alcohol.

Oil of Spearmint.—The following data were determined in the examination of four lots:

\[ d_{15^\circ}/15^\circ \] ............... 0.933 to 0.940
\[ aD \] 20\(^\circ \] ...................................... -45.3\(^\circ \) to -50.2\(^\circ \)
\[ aD \] 20\(^\circ \] ...................................... 1.4880 to 1.4885
Soluble in an equal volume of 80 per cent. (by volume) alcohol.

Cod-liver Oil.—The following data were obtained in examining forty-eight lots:

\[ d_{15^\circ}/15^\circ \] ............... 0.919 to 0.929
\[ aD \] 20\(^\circ \] ...................................... 1.4775 to 1.4800
Iodine value (Wijs) ............... 138.4 to 194.0
(Only five lots were found with iodine values below 150.)
Saponification value ............... 178.0 to 191.7

Oil of Myristica.—Eleven lots were examined, the limits being as follows:

\[ d_{15^\circ}/15^\circ \] ............... 0.904 to 0.925
\[ aD \] ........................................... +17\(^\circ \) to +20.3\(^\circ \)
Soluble in 1 to 3 volumes of 90 per cent. (by volume) alcohol.

Olive Oil.—Twenty-four lots were examined with the following results:

\[ d_{15^\circ}/15^\circ \] ............... 0.915 to 0.918
\[ aD \] 20\(^\circ \] ...................................... 1.4683 to 1.4693
(Two lots were found having refractive indices at 20\(^\circ \) of 1.4706 and 1.4708.)
Iodine value (Wijs) ............... 78.8 to 86.5
Saponification value ............... 185.3 to 195.4
Oil of Pimenta.—Fifteen lots were examined with the following results:

\[
\begin{align*}
\text{d}^{15} / \text{i}^{15} & \quad 1.034 \text{ to } 1.046 \\
\alpha D & \quad -0.4^\circ \text{ to } -3.0^\circ \\
\text{Eugenol} & \quad 70 \% \text{ to } 80 \% \\
\end{align*}
\]

Soluble in from 1 to 2\(\frac{1}{2}\) volumes of 70 per cent. (by volume) alcohol.

Castor Oil.—Fourteen lots varied within the following limits:

\[
\begin{align*}
\text{d}^{15} / \text{i}^{15} & \quad 0.960 \text{ to } 0.967 \\
\alpha D & \quad 1.4780 \text{ to } 1.4802 \\
\text{Iodine value (Wijs)} & \quad 82.0 \text{ to } 86.9 \\
\text{Saponification value} & \quad 176.4 \text{ to } 180.9 \\
\end{align*}
\]

Oil of Rose.—The following data were obtained in examining six lots:

\[
\begin{align*}
\text{d}^{30} / \text{i}^{15} & \quad 0.856 \text{ to } 0.859 \\
\alpha D & \quad -1.3^\circ \text{ to } -2.7^\circ \\
\alpha D & \quad 1.4610 \text{ to } 1.4665 \\
\text{Congealing point} & \quad 19^\circ \text{ to } 21^\circ \\
\text{Saponification value} & \quad 11.9 \text{ to } 17.1 \\
\end{align*}
\]

The saponification values for thirty-four lots varied from 11.9 to 22.2, and the optical rotation from \(-1.3^\circ\) to \(-3.6^\circ\).

Oil of Rosemary.—Thirteen lots varied within the following limits:

\[
\begin{align*}
\text{d}^{15} / \text{i}^{15} & \quad 0.900 \text{ to } 0.913 \\
\alpha D & \quad +1.3^\circ \text{ to } +14.2^\circ \\
\end{align*}
\]

Oil of Savin.—Twenty-one lots were examined with the following results:

\[
\begin{align*}
\text{d}^{15} / \text{i}^{15} & \quad 0.966 \text{ to } 0.925 \\
\alpha D & \quad +39^\circ \text{ to } +56.3^\circ \\
\end{align*}
\]

Soluble in \(\frac{1}{2}\) to 1 volume of 90 per cent. (by volume) alcohol.

Oil of Sassafras.—Fourteen lots varied within the following limits:

\[
\begin{align*}
\text{d}^{15} / \text{i}^{15} & \quad 1.07 \text{ to } 1.08 \\
\alpha D & \quad +2.6^\circ \text{ to } +3.9^\circ \\
\end{align*}
\]

Soluble in 1 to 2 volumes of 90 per cent. (by volume) alcohol.

Croton Oil.—Eight lots were examined with the following results:

\[
\begin{align*}
\text{d}^{15} / \text{i}^{15} & \quad 0.942 \text{ to } 0.948 \\
\alpha D & \quad 1.4784 \text{ to } 1.4785 \\
\text{Iodine value (Wijs)} & \quad 104.0 \text{ to } 116.0 \\
\text{Saponification value} & \quad 200.0 \text{ to } 235.0 \\
\end{align*}
\]

Phenol.—Eighteen lots were found to melt at from 40° to 41°, and to contain from 96 per cent. to 98.4 per cent. of absolute phenol.
Phenyl Salicylate.—Twenty-four lots varied in melting-point from 40.5° to 43°.

Pilocarpine Hydrochloride.—Fourteen lots melted at temperatures from 194° to 199° C.

Pilocarpine Nitrate.—Five lots melted at temperatures from 167° to 172° C.

Pilocarpus.—Only the Pilocarpus microphyllus has a high enough alkaloidal content to meet the official requirement; four lots of this species assayed in 1908 were found to contain 0.78 per cent., 0.96 per cent., 1.14 per cent., and 0.98 per cent. of alkaloids. During 1909 five lots were assayed with the following results: 0.94 per cent., 0.83 per cent., 1.23 per cent., 0.91 per cent. and 0.98 per cent. Three lots of Pilocarpus Jaborandi assayed, 0.15 per cent., 0.35 per cent. and 0.13 per cent.

Piperine.—Four lots were found to have melting points of 128° C. to 130° C. The melting point is given in “Beilstein” as 128° C. to 130.5° C.

Potassium Bicarbonate.—A large number of lots have been found to vary from 98 per cent. to 99.9 per cent., most lots being between 98.5 per cent. and 99.5 per cent.; one lot was found to be only 96 per cent.

Potassium Chlorate.—Potassium chlorate, on account of the practice of shipping in barrels and kegs, frequently contains particles of wood and paper fiber which might make the manufacture of tablets somewhat dangerous. One lot was shipped in kegs which had been charred on the inside; they were carelessly lined with paper, and the chlorate contained many particles of charcoal and partially charred wood.

Resorcinol.—Seventeen lots have been found to have melting points from 108° C. to 110° C.

Salicin.—The melting points of seven lots were from 196.5° C. to 198° C.

Santonin.—Sixteen lots melted between 169° C. and 171° C.; one lot at 166° C. and one at 168° C. A melting point requirement of from 169° C. to 171° C. would probably be satisfactory.

Sodium Carbonate.—Lots of the monohydrated salt have been found to vary from 83.5 per cent. to 87 per cent. of sodium carbonate. Most of the salt sold as dried sodium carbonate is the monohydrated salt.

Exsiccated Sodium Phosphate.—The amount of water in a large number of lots examined varied from 0.2 per cent. to 14.5 per cent.

Sulphonmethylnitroso.—Five lots had melting points between 75° C. and 76° C., one lot melted at 71° C. Six lots of Bayer & Co.’s trional had melting points between 75° C. and 77° C.

Sulphonmethane.—Six lots melted between 125° C. and 125.5° C. Eleven lots of Bayer & Co.’s sulphonal had melting points between 125° C. and 126° C.

Terpin Hydrate.—Twelve lots had melting points between 115° C. and 117° C.

57
Vanillin.—Twenty-four lots melted between 80° C. and 80.5° C., two lots at 77.5° C., one at 79.5° C., and three at 81° C.

Veratrum.—In 1908 five lots assayed 1.33 per cent., 1.9 per cent., 1.94 per cent., 1.21 per cent., and 1.66 per cent.

In 1909 four lots assayed 1.60 per cent., 1.53 per cent., 1.69 per cent., and 1.85 per cent.

The foregoing results include only those which it was thought might be of assistance to the revision committee in establishing standards. Only data based upon a considerable number of determinations have been given, and in most cases data upon well established points have been omitted. As this is not intended to be a report upon market conditions or adulterations, lots which have been found to be adulterated or of poor quality have not been included except in a few cases; where no mention is made of such lots only very few have been found in proportion to the number reported upon. The limits given are not recommended for adoption by the Pharmacopoeia, but only for consideration in connection with other published data.

Mr. Scoville: I differ with my friend Eldred about the 15° C., and I do not favor 25, for this reason; all of the apparatus so far as I recall now, is standardized at 20° C., and for that reason it is the temperature adopted by the Bureau of Standards at Washington, and also the standard adopted by the International Society of Applied Chemistry—I have forgotten the exact title of that Association—and it seems to me that to use an apparatus at 20° C., would be rather a peculiar situation; we would have to adjust all our apparatus.

Mr. Eldred: In that connection, I would like to say that all the apparatus we have in our laboratory is standardized at 15° C.

The Chairman: We have one more paper, which is in print, entitled “Microscopical Examination of Extracts of Belladonna and Scopola,” by Mr. E. N. Gathercoal. Mr. Gathercoal is not here, and Mr. Clark will say a few words in regard to the paper.

The following is the full text of the paper:

MICROSCOPICAL EXAMINATION OF BELLADONNA EXTRACT.

E. N. Gathercoal.

A question recently arose as to whether extract of belladonna root or extract of scopola could be legally used in the manufacture of belladonna plasters, provided the plaster contained the official requirement of mydriatic alkaloids. This led to the question as to the possibility of distinguishing, with the microscope, between extract of belladonna leaf, extract of belladonna root and extract of scopola. Upon investigation it was found that sufficient characteristic vegetable tissue could usually be obtained from an extract to identify the drug from which the extract was made.

A portion of the extract about the size of a wheat grain is smeared on a glass slide and viewed with a low power (75 diameters) of the microscope. The most prominent objects seen in the field of view, if the extract is of
belladonna root or scopola root, are a large number of rhombohedron-like crystals, sometimes quite irregular and measuring 25 to 150 microns in longest diameter. Another striking feature in specimens of some of the root-extracts is the considerable amount of fixed oil globules present. In but a few instances is starch found and very seldom cellular tissues. The extracts of belladonna leaf do not show the crystals nor fixed oil as in the root extracts, but present an almost homogeneous appearance.

A similar portion of the extract is smeared on a slide and covered with a drop of water and a cover glass. The crystals rapidly dissolve, the oil globules become more distinct, and starch may be found. The starch and oil are distinguished by the use of iodine solution. In the leaf-extracts some dark masses of oily chlorophyll may separate out.

To a similar smear of the extract a drop or so of alcohol is added and now the crystals do not dissolve, but the oily substances do gradually disappear.

One gram of the extract is well mixed in a test-tube with 25 Cc. of 50 per cent alcohol, rubbing and stirring the extract into the fluid with a glass rod. The mixture is allowed to stand several hours until the precipitate settles out or it may be centrifuged at once. The precipitate in most cases is quite voluminous and falls slowly. The clear, supernatant liquid is poured off as completely as possible and a mount prepared from the precipitate. This may show starch, oil and cellular tissues, but so much brown extractive is present as to largely obscure other material.

To the remainder of the precipitate is added about 5 Cc. of concentrated hydrochloric acid, which dissolves the starch and the brown extractive, but does not injure the vegetable tissues. Then about 10 Cc. of alcohol is added, the precipitate allowed to subside and the fluid decanted. The use of the centrifuge for throwing out precipitate permits of a great saving of time. The precipitate, which in most cases is now very small in amount, is transferred to a slide and mounted in the few drops of fluid adhering to it. Or it may be transferred with several drops of liquid to a watch glass or small white crucible, nearly dried with gentle heat and then scraped onto a slide and mounted in a drop of chloral hydrate solution.

In these mounts particles of cellular tissue that were present in the extract are seen. The amount of these particles varied widely in the different extracts examined. There were found pieces of thin-walled parenchyma filled with partially destroyed starch, masses of parenchyma and tracheal tubes, separated pieces of tracheal tissue, smaller and yet smaller pieces of parenchyma tissue and cells, occasionally a fiber, some extraneous tissues as cotton fibers, and in one instance several well-defined cells of cocoanut shell, and finally in some of the mounts many pieces of black substance resembling charred or carbonized matter.

The tracheal tissues were used as the principal means of distinguishing between scopola and belladonna roots. Some of the tracheal tubes of belladonna have on their walls well-defined, slightly elongated, bordered pits and none of the tubes of scopola have such markings. Some of the tubes
of scopolia have on their walls much elongated, very prominent slits with the portions of the walls between the slits heavily thickened, giving a very characteristic reticulate appearance. None of the belladonna tubes have such markings. However, some of the belladonna tubes have pores not bordered, and more elongated, so as to present a rather finely reticulate appearance, and also, some of the scopolia tubes have the slits on the walls rather shorter and approach in appearance the tubes of belladonna just mentioned.

The material examined consisted of twelve extracts, Nos. 1 to 12, submitted to me for examination as extract of belladonna; one extract of belladonna root, No. 13, two extracts of belladonna leaf, Nos. 15 and 16, one extract of scopolia root, No. 14, all purchased in original packages in the open market, and an extract of belladonna root, No. 17, an extract of scopolia root, No. 18, and an extract of belladonna leaf, No. 19, all personally prepared from selected drugs according to the U. S. P.

</table>
In the above tabulation "pieces" of scopola or belladonna refers to pieces or masses of characteristic tracheal tissue as previously described.

Referring to No. 3, one of the commercial extracts, would say that this extract yielded no tracheal tissue after repeated trials. However, as it contained numerous crystals characteristic of the root extracts and much fixed oil characteristic of belladonna root extract, it is probably belladonna root extract. No. 6 contained such a mass of black, charred pieces and so much extraneous matter that it was impossible for me to separate out characteristic tracheal tissue and my conclusion that it is scopola root extract is open to question.

Nos. 13, 14 and 15, labeled "Extract of Belladonna Root," "Extract of Belladonna Leaf," and "Extract of Scopola," respectively, over the name of a well-known pharmaceutical manufacturer, contained but little tracheal tissue and no charred matter. However, the extract of scopola certainly contained belladonna extract if it was not all belladonna.

No. 16, labeled "Extract of Belladonna Leaf," produced, upon mixing with dilute alcohol, a copious, white precipitate, insoluble in water or alcohol, but soluble in acids without effervescence. Under the low power of the microscope this powder appeared as large irregular crystals. Upon ignition the ash amounted to nearly 10 per cent. It contained magnesia. No tracheal tissue was determined in this extract, though from the presence of a very little greenish oil it is probably leaf extract.

Referring to Nos. 17, 18 and 19, the extracts which were carefully prepared in the laboratory, using filter paper beneath the powdered drug in the percolator, would say that the amount of cellular tissue present was small, but sufficient characteristic tracheal tissue was obtained from each extract but one, the belladonna root extract, to identify the extract.

**THE FIXED OILS FOUND IN THE EXTRACTS.**

Some of the powdered belladonna root from which the extract was prepared according to the U. S. P., was extracted for six hours with petroleum benzine in a Soxhlet extraction apparatus to determine, if possible, the amount of fixed oil present in the root. After the evaporation of the benzine, a slight residue amounting to .75 per cent. remained, and this appeared to be mostly a yellowish fixed oil. Some of the extract prepared from this belladonna root was extracted in a similar manner and yielded a residue, 3.26 per cent., most of which appeared to be a fixed oil.

The amount of fixed oil is apparently greater in belladonna root than in scopola root, though the personally prepared scopola root extract contained more oil than the commercial scopola root extracts.

**THE CRYSTALS FOUND IN THE EXTRACTS.**

The crystals, apparently so abundant in the root extracts, were at first thought to be milk sugar added to the commercial extracts, but when they
were found in greatest abundance in the home-made extracts (both of scopola root and belladonna root) to which no milk sugar was added, it became evident that probably these crystals were not milk sugar. A portion of the extract of belladonna root prepared in the laboratory was dialysed for 24 hours and the dialysate tested for sugar. The solution gave a dextrogyrate reading on the polariscope and reduced Fehling's solution. Quantitatively with Fehling's, it amounted as glucose to about 5 per cent. of the extract. Upon evaporation of a portion of the dialysate to constant weight the residue amounted to more than 15 per cent. of the extract. Upon ignition, the ash obtained from a portion of the dialysate amounted to .8 per cent. of the extract.

The amount of these crystals appears to be about the same in the scopola as in the belladonna root extracts, but the amount in some of the commercial extracts was much less than in the home-made extracts.

THE COLOR OF THE EXTRACTS AND THEIR SOLUTIONS.

The color of the extracts was quite similar, especially where the surfaces of the extracts as found in the jars were not cut into, the color being in all cases a very dark brown to black. Freshly-cut surfaces, however, varied somewhat in color, some being a darker brown than others and the leaf extracts showing a decided green color. The solutions or mixtures in dilute alcohol, however, varied much in color, the root extracts ranging from a light straw color to a very dark brown, the leaf extracts showing various shades of green. At the first tabulation of the commercial extracts it appeared as though the solutions of the scopola extracts were uniformly much darker than the solutions of the belladonna extracts, but this I hold to be not strictly so, for the scopola root extract prepared by myself formed a solution nearly as light in color as any of the belladonna extracts.

Nearly all of these extracts were assayed and in each case the alkaloidal content fully met the U. S. P. requirement for extract belladonna leaves. It is assumed the alkaloids were the mydriatic alkaloids.

**The Chairman:** That brings us to the end of our program for this morning, and a motion to adjourn is in order.

On motion, the Section adjourned to 3 o'clock, p. m.

**Adjourned Session.**

The Section assembled promptly at 3 o'clock, p. m., and was called to order by Chairman Wilbert.

**The Chairman:** Mr. Kebler has a paper which is on our program for to-morrow morning, but as he is leaving the city to-day, he desires to present it now. We will be
THE QUALITY OF MEDICINAL HYDROGEN DIOXIDE AT PRESENT ON THE MARKET.

BY LYMAN F. KEBLER.

Hydrogen dioxide is undoubtedly the most popular refined germicide and antiseptic at present on the market. It is also largely used by the medical profession. Unfortunately, however, it is prone to deteriorate more or less rapidly. Numerous investigations have been made with a view of devising methods to produce a stable product. The results in the past, however, have not been uniformly satisfactory. With this condition obtaining, it was decided to make an investigation of the quality of the various brands on the market for the purpose of arriving at a fair basis of action. In order to eliminate disturbing factors as far as possible, it was decided to have the work carried on by two independent workers at two different points, namely, Washington, D. C., and Nashville, Tennessee. The question of obtaining fresh material was also a desideratum and carefully considered. In order to provide for this, the goods were ordered from two wholesalers, with instructions that fresh material was desired. The work was begun in the fall of 1907 and continued over a period of from nine to twelve months. Mr. L. E. Warren conducted the experimental work in Washington and Dr. E. A. Ruddiman at Nashville.

RESULTS OF INVESTIGATION MADE IN WASHINGTON.

Determination of hydrogen dioxide. Unless otherwise stated, the methods prescribed by the United States Pharmacopœia, Eighth Revision, for testing the quality and purity of hydrogen dioxide solutions, were employed. In view of the fact that the value of a hydrogen dioxide solution is largely judged by the actual amount of hydrogen dioxide present, the various products were analyzed with particular reference to this point as rapidly as possible after receiving same. The Pharmacopœial method was used, excepting that the measured samples were weighed and the percentage computed on this basis. The results obtained will be found in columns headed "U. S. P. Method." The results clearly show that a large percentage of the samples examined by this method contain about 3 per cent. of hydrogen dioxide. In order to check the permanganate-sulfuric acid method for determining hydrogen peroxide and compare it with other standard methods it was decided to analyze the samples by
three additional methods, namely, the iodine method, the gasometric methods, using sulphuric acid and potassium permanganate in one and manganese dioxide and sulphuric acid in the other. In each case the hydrogen dioxide solution was measured out and weighed, as stated above, in connection with the pharmacopœial method, and aliquot parts of same employed. The iodine method proposed by Rupp* was carried out as follows:

1 gram of potassium iodide was placed in a 250-Cc. Erlenmeyer flask, 10 Cc. of 10 per cent. sulphuric acid added, and as soon as the salt was dissolved, 10 Cc. of the diluted peroxide solution 1:10 were run in by means of a burette. The flask was then covered with a watch glass and allowed to stand 30 minutes. Then about 200 Cc. of distilled water were added and the liberated iodine titrated with $\frac{N}{10}$ sodium thiosulphate solution, using starch solution as indicator. This method proved somewhat less satisfactory than the pharmacopœial method, being less rapid, and giving less concordant results. Each assay was made in duplicate, and the mean result given in accompanying table, in column headed "Iodine Method."

The samples were next analyzed by measuring the same volumes of oxygen liberated by means of manganese dioxide and potassium permanganate respectively, in the presence of sulphuric acid. It was found that Lunge's nitrometer, with a two-way stop cock did not give satisfactory results, when the reaction took place inside of the instrument. After making a number of experiments, the following apparatus and procedure were decided upon.

**Manganese Dioxide Method:** The apparatus consists of a 50-Cc. side arm distilling flask closed with a perforated rubber stopper through which the delivery stem of a glass-stoppered burette has previously been passed. The side arm of the flask is connected to the nitrometer by means of tightly fitting rubber tubing of any convenient length and securely wired at each end to prevent leakage. The burette is fastened loosely in a Bunsen clamp in such manner that the burette and flask can be shaken freely in one plane. The nitrometer is filled with water and the level adjusted. About 1 gram of finely powdered manganese dioxide is placed in the side arm flask and 10 Cc. of 10 per cent. sulphuric acid added. 10 Cc. of the hydrogen peroxide solution to be tested are diluted to 100 Cc. and a portion placed in the burette. After sufficient of the solution is run out to fill the delivery stem of the burette the stopper (with attached burette), is snugly fitted into the neck of the generating flask, and the level of the water in the nitrometer adjusted so as to equalize the pressure within the system. 10 Cc. of the diluted dioxide solution are then slowly allowed to run into the generator through the burette. After shaking the

* Arch. Pharm., 238—156, 1900.
flask to liberate the dissolved oxygen as completely as possible the level is again adjusted and the temperature and pressure noted. A correction of 10 Cc. (the volume of solution run into the generator), are then subtracted from the reading, and the remainder reduced to conditions at 760 mm. and 20° C.

The results obtained will be found in column headed “Gasometric Analysis, Volumes of Oxygen Evolved by MnO₂.” The potassium permanganate method was carried out in the manner described under the manganese dioxide method above, except that the dilute sulphuric acid and dilute hydrogen dioxide solutions were placed in a generating flask and sufficient \( \frac{8}{3} \) potassium permanganate solution added from a burette to give a pink color to the solution. The results obtained by this procedure will be found in column marked “Gasometric Analysis, Volume of Oxygen Evolved by KMnO₄.” The results obtained by the gasometric methods are fairly concordant but not as satisfactory as those with the Iodine and official methods. In general, however, the gasometric methods are less reliable than the last two named, being too dependant upon slight variation in temperature, pressure, leakage and other factors. In order to determine the rate of decomposition, the samples were re-examined for percentage of hydrogen dioxide by the pharmacopceial method at the expiration of three, six, ten and twelve months after the initial analysis. The results are recorded in the accompanying table.

After determining the percentage of hydrogen peroxide in the various brands by the methods outlined above, they were examined for preservatives, acidity, non-volatile matter, fluorides, arsenic, barium, etc.

**PRESERVATIVES.**

The principal labels on the packages, as well as the analytical results obtained, show that a large proportion of the hydrogen dioxide solutions contain small quantities of acetonilide. The acetonilide was determined by shaking a 50-Cc. sample of H₂O₂ twice with ether, once with chloroform, combining the several extracts in a tared beaker and drying at 75° C.

Experiments made with samples of hydrogen peroxide containing known quantities of acetonilide showed that this method removed about 95 per cent. of the amount present. The acetonilide was identified by its physical and chemical properties. The indo-phenol reaction proved to be the most satisfactory. The presence of borax and boric acid were also tested for with negative results.

A number of samples which were found to be free from acetonilide possessed a noticeable odor of aldehyde after being kept for some time. It was suspected that alcohol had been used as a preservative, but distillation from both acid and alkaline media failed to give a distillate in which alcohol could be detected by the iodoform test. By applying the method direct, however, good results were obtained. The distillate from these
gave the general reactions for aldehyde with fuchsin and sulphurous acid and with Tollen's reagent. The presence of fluoride was indicated in several products, but the results were not conclusive. Caffeine was found in several packages of one brand.

RESULTS OBTAINED IN NASHVILLE.

All of the samples were examined as to purity, quality and strength, by the pharmacopœicl methods. The investigation covered two series, one begun in October, 1907, and the other in December of the same year. The several samples were re-examined at intervals of time as indicated in the table. The acetonilide was extracted by means of chloroform, it having been shown that less than one-fiftieth of a grain could be detected by the phenyl-isocyanide reaction.

NOTES BY THE AUTHORS.

As indicated above, the value of a solution of hydrogen dioxide is largely judged from the percentage on hydrogen dioxide present. The investigations were begun in October, 1907, and continued over approximately one year. The results obtained by the gasometric methods and the iodine method do not materially vary from the pharmacopœicl method, and for that reason the latter method will be made the basis of comment. The Pharmacopœia states that the hydrogen dioxide solution should contain when fresh about 3 per cent. by weight of absolute hydrogen dioxide, corresponding to about ten volumes of available oxygen.

A review of the results obtained by the first examination shows that twenty-one of the samples fall below the 3 per cent. basis and eight fall below a 2.75 per cent. basis.

Experience of trade conditions leads to the belief that it is not necessary to keep hydrogen peroxide solutions on hand longer than from five to six months, the latter being the outside limit.

A review of the results obtained five and six months after the first examination shows that 24 of the samples examined lost 10 per cent. and over of the original percentage content of hydrogen dioxide, while on a 15 per-cent. basis 21 were found defective, which is only 3 less than on the 10 per-cent. basis. The 15 per-cent. basis has therefore little to its credit. The point, however, may be raised that this commodity is less stable in warm than in cold weather. This is a cherished belief, which is, however, not well supported by this investigation. The degree of deterioration taking place during the first five and six months and between five and six months and nine and ten months, respectively, which latter covers the summer months, does not differ materially from that noted over similar periods of time in cooler weather. It should moreover be noted that these observations were made after the samples were at least five or six months old and deterioration had set in, a condition favorable for decomposition.
The results of this work undoubtedly show that acetanilide retards the deterioration of hydrogen peroxide solutions. The results, however, are not uniform. For example, two samples of hydrogen peroxide, made by the same firm, both containing acetanilide, one will deteriorate rapidly, while the other is fairly stable. What the cause of such apparent abnormalities may be, we are at present unable to determine. There are probably numerous contributing factors, but one undoubtedly is the difference obtaining in the process of manufacture. The absence of acetanilide in a number of brands and the slow rate of deterioration of some show, however, that acetanilide is not a necessary agent to prevent or retard decomposition. Hydrogen peroxide solutions containing acetanilide sooner or later develop a yellowish or brownish tint and at the same time an odor resembling nitrobenzol. A preparation so contaminated or deteriorated should no longer be dispensed or sold for medicinal purposes. To what extent the presence of nitrobenzol and similar agents are objectionable has not been established. The Pharmacopoeia does not recognize the use of acetanilide as a preservative, antiseptic or otherwise, yet many packages bear labels declaring the presence of acetanilide and at the same time designate the article to be a pharmacopoeial product. This is certainly inconsistent. The object of adding the acetanilide is not because of its antiseptic property, as indicated upon certain labels, but because of its apparent inhibiting influence on deterioration. The presence of acetanilide was declared in 72 samples, and found in 70. This chemical was found in 13 samples, none of the labels of which bore a statement or indication as to its presence.

ACIDITY.

The results on acidity show that a large majority of the products are excessively acid. This may be interpreted that the standard equivalent to $\frac{3}{2}$ Cc. of $\frac{X}{10}$ sulphuric acid for 25 Cc. of the solution, is too rigid. By placing the upper limit at 3 Cc. of $\frac{X}{10}$ sulphuric acid for 25 Cc., 51 would still be excessively acid and by placing the upper at 4 Cc., 22 would still be above the limit. A certain amount of acidity may result from the oxidation or disintegration of the acetanilide present. This is a point, however, which should be provided for by the manufacturer who uses the chemical. The maximum acidity prescribed by the United States Pharmacopoeia does not appear to be exacting, particularly when it is called to mind that hydrogen peroxide solutions are largely used as mouth washes. If this product should contain an excessive amount of free acid, it would of necessity exert a deleterious influence on the teeth. Numerous experiments have been made relative to determining the acidity present in hydrogen peroxide solution by the Pharmacopoeia and other methods, with the results that phenolphthalein could be substituted with advantage by methyl orange. Experience and experiments furthermore show that the
free acidity can readily be determined by direct titration, using phenolphthalein as indicator. Exactly why the present pharmacopoeial method for determining acidity is introduced, is not clear, neither has a satisfactory reason for its inclusion been given.

NON-VOLATILE MATTER.

The results show that a comparatively small number contain an excessive amount of solids. It appears that there should be little difficulty in properly adjusting this point, particularly in view of the fact that the majority of those containing excessive amounts of solid material are made in one and the same factory. One manufacturer states definitely that the amount of non-volatile matter is in excess of that prescribed by the Pharmacopoeia. The solid material on examination was found to contain one or more of the following; chlorides, phosphates, sulphates and acetaldehyde. In no case was the presence of fluorides established, but in several instances a trace of metals was noted. Tests made on the solid material show that the acetaldehyde was neither completely decomposed or volatilized at \(120^\circ\) C.

As is well known to the medical and pharmaceutical profession, hydrogen peroxide was once considered a very efficient remedy in the treatment of diphtheria, but it is now known to be virtually worthless. In spite of this fact, such statements as the following are still used; cures quickly nose, throat and chest diseases.

Notwithstanding the fact that hydrogen peroxide solutions are known to be more or less unstable, manufacturers do not hesitate to place such statements as the following upon their labels: "Permanent," "Guaranteed unsurpassed in keeping qualities," "a permanent x x x preparation," "unsurpassed in strength and keeping qualities," "full 10 volumes strength," etc., but analysis shows that the latter is less than \(\frac{3}{4}\) the standard strength. Why such statements should be used in connection with products of this character is difficult to conjecture, particularly when it is well known that they are liable to lead to trouble.

1 No denomination given.
Mr. Francis: Mr. Chairman, I don't know that I would offer anything on this subject, but for the fact that I have been very much interested in hydrogen peroxide for about three years, and this fact, and the further fact that I have indirectly devoted a great deal of study to the principles involved in the manufacture of hydrogen peroxide, and also a very close and constant study of a comparison of all the various brands of peroxide manufactured in the United States and abroad, as well; and this shall be my excuse for imposing upon your time for a few moments.

We can all remember when hydrogen peroxide was manufactured by the retail druggist, in very small quantities, and sold by him at what we would now regard as an exorbitant price, for the very good reason that it decomposed from the very moment of its production. Hydrogen peroxide is now used in enormous quantities; there is enough produced in the United States every year to float the “Lusitania.” Whether this very wide use of it by the laity is wise, I will not offer an opinion. It is sold in practically every retail store in the country, so the matter of the life or preservation of hydrogen peroxide is a live topic, from the standpoint of the retail druggist. What we have learned of the necessary conditions surrounding the production of hydrogen peroxide has been of very great value in increasing the stability of this product, so that it can now be logically regarded as an article of commerce, and can be shipped and distributed economically, and at a reasonably economical price. There still remains a great deal to be learned about it—a great deal—more than we know at the present time. One of the most interesting things, of course, would be the study of a preservative, which would delay the decomposition of the hydrogen peroxide, and it was discovered a few years ago that the most potent factor to prevent this decomposition was acetanilide. A great many substances have been proposed, and I find to my astonishment that some chemists, who ought to know better, who have written dissertations on the subject, have quoted from statements made as far back as thirty, forty and fifty years ago by German chemists, French chemists, English chemists and various other chemists, recommending boric acid, and in some cases borax, magnesia and other similar soluble salts—the veriest nonsense that any man ever embodied in an argument, I think. Of course we know that any alkali leads to the decomposition of peroxide. We know that its stability is in almost direct proportion to the excess of free acid. We do know—at least I feel that I know, from investigation, that the presence of most of the insoluble salts has practically no effect whatever on the stability of hydrogen peroxide. The one potent factor, however, is the presence of metals. I think I am correct in saying that the most potent is copper. Iron cannot be eliminated altogether, but it is also very potent. Iron is found in the ordinary materials employed in its manufacture, in some degree, and it is impossible to remove every trace of the iron.

Now as regards the matter of acetanilide, it would of course be desirable if hydrogen peroxide could be marketed without acetanilide or any extraneous matter whatever. The hydrogen peroxide made by the best methods, and as pure as is practicable, will under ordinary circumstances retain its full strength for six months or longer; at the same time the life of hydrogen peroxide can be extended under ordinary conditions to twelve months, and sometimes eighteen months, by the use of a small portion of acetanilide, so small that a man would have to swallow a great amount of hydrogen peroxide in order to get an ordinary dose of acetanilide.

I do not think there is any sense whatever in any one making the claim that acetanilide should be added to hydrogen peroxide because of its antiseptic effect; it is used in too small quantities, although it is well known to physicians and surgeons that acetanilide applied is a very good germ destroyer. It has been used very much in the powdered form, but its use is objectionable on account of the danger of over oxidation. But I want to make this statement in closing my remarks, that taking any hydrogen peroxide, regardless of its quality, the life of that particular grade of peroxide will be doubled by
the addition of a minute quantity of acetanilide. Now I have not the proof of that assertion to offer you to-day, but I will be very glad to publish it, and shall do so in the next few months, as the result of a long series of careful experiments and comparative tests, made for a period extending back nearly four years. I can not make that statement too emphatic—it has its preservative effect irrespective of the quantity used.

Mr. Remington: I do not want to ask impertinent questions, but I would like to have Dr. Francis tell us about the decomposition. Now there is a period, is there not, when, with the addition of acetanilide, there is no odor whatever? But I would like to ask, when that odor appears, is that an indication that the hydrogen peroxide itself is deteriorating, and does that mean that that decomposition goes on, and that acetanilide ceases then to be a preservative?

Mr. Francis: Very largely so. As oxygen is given off by the decomposition of the hydrogen peroxide; it attacks the acetanilide; I think I am correct in the statement that a certain amount of color is produced. If decomposition has progressed to a sufficient extent it will produce a little color, and I should say when hydrogen peroxide develops a distinct odor or color, it should not be used or dispensed. But I would also supplement that with this further assertion, that there is no power under heaven, so far as we know now, that will prevent the decomposition of hydrogen peroxide sooner or later, and that it is better for the druggist, or the physician or the layman to be placed on his guard, and not to dispense or to use hydrogen peroxide which has developed an odor, than it is for him to dispense or to use a bottle containing nothing but water, and from which all the oxygen has passed off by the evolution of gas. In other words, I would look upon this preservative as having the further effect of a safe-guard to prevent the use of a deficient hydrogen peroxide.

Mr. C. E. Caspari: In connection with the oxidation of acetanilide by hydrogen peroxide, I think there is some process of oxidation that is not entirely understood yet, because I have frequently seen samples of peroxide which apparently, as far as we knew, were identical in every respect, as to age, and quantity of acetanilide contained in them and yet in the same period of time some of these would develop the odor of nitrobenzene, and become yellow, while others would not. What the reason of that is, I do not know, but it shows that there is something there which is not clearly understood, concerning the oxidizing power of peroxide on acetanilide.

Mr. Kebler: My opinion coincides with Mr. Caspari's on the question of the oxidation of acetanilide.

The Chairman: The next paper is entitled "Physiologic Standardization of Cardiac Stimulants and Depressants," by Dr. T. Stotesbury Githens; this paper will be presented, together with a comparison of such standardization, with some results obtained by chemical assay, by Mr. Charles E. Vanderkleed.

Mr. Vanderkleed here presented Dr. Githens' paper, as well as his own.

PHYSIOLOGIC STANDARDIZATION OF CARDIAC STIMULANTS AND DEPRESSANTS.

BY THOMAS S. GITHENS.

TOGETHER WITH A COMPARISON OF SUCH STANDARDIZATION WITH SOME RESULTS OBTAINED BY CHEMICAL ASSAY.

BY CHAS. E. VANDERKLEED.

In spite of the large amount of physiological work which has been done with the vegetable drugs in order to determine the method by which they
act and the organs and processes which are first and most markedly affected, we find very little in the literature in regard to determination of the strength of these drugs or the amount required to produce certain effects. In the text books on therapeutics we find a distinction drawn between the effects of "small" and of "large" or "toxic" doses on the various animals used for experimental purposes, but very rarely do we find any exact statement as to what amount of the drug per gram of animal constitutes such a dose.

For this reason it has seemed interesting as well as important to determine the exact amount of various drugs which were required to produce definite effects in laboratory animals and to determine also which method of testing was best suited to each drug.

Commercially this study is of importance on account of the desire of manufacturers of these drugs and their products to put on the market preparations of definite physiologic strength, from drugs the chemical study of which is not a criterion of activity. My studies have been largely limited to such drugs for this reason.

The drugs whose standardization I will consider are Apocynum, Aconite, Convallaria, Digitalis, Gelsemium, Scilla, Strophanthus, and Veratrum. These drugs fall into two groups; those which raise blood pressure, the so-called digitalis series, Apocynum, Convallaria, Digitalis, Scilla, and Strophanthus; and those which lower blood pressure, Aconite, Gelsemium, and Veratrum.

We will consider, first, the drugs of the digitalis series. Three methods are available for the purpose of quantitative determination of their activity.

1. The effect on the isolated heart of the frog or turtle.
2. The effect on the blood pressure.
3. The amount required to cause death.

As the effect on the heart is that which makes these drugs useful in practical medicine, it is often stated that the best method of testing them is directly on the heart. The effect on this organ can be studied to the exclusion of all other factors by the following method. The heart of a frog or turtle will continue to beat, if it is placed in a solution of the proper salts, after its removal from the body. If the heart is cut into longitudinal strips, each of these will continue to beat under proper conditions, and may live for two or even three days after removal from the body. It would seem that by adding the drug to be tested to the liquid in which the strips were suspended, the effect of this on the heart itself might be determined with great accuracy. This would be true but for the fact that organs isolated from the body and kept under artificial conditions are very susceptible to slight alterations in their surroundings—so much so, that if four strips are cut from the same heart and are kept under apparently identical conditions, they may show great differences among themselves, and although the
effect of the addition of a given drug to the solution might easily be seen in the alteration of the rhythm, the differences between the reaction of different strips would be greater than that between different specimens of the same drug. In work of this sort which I have done, I found that the difference in the effect of a given quantity of a drug and twice this amount was not very marked, although there was generally a fairly marked difference between a given amount and four times as much. A method which gives results showing a variation of 50 per cent. in one direction or the other can of course not be depended on for quantitative standardization.

The second method, the effect on the blood pressure, has also something in its favor, inasmuch as the stimulating effect of these drugs on the heart is in more or less direct proportion to the effect on the blood pressure. If the effect of drugs on the blood pressure is studied, it will be found that the rise following an injection is not in proportion to the dose given. A small dose will cause a perceptible rise, but twice this dose will not cause twice this rise. In fact, we find that a certain dose brings about almost a maximal rise and that increasing the dose will merely increase toxic phenomena, so that the pressure will fall more rapidly than after the smaller dose. The effects of large and small doses are thus distinguished with difficulty and the same is pari passu, true of equal doses of strong and weak preparations. It is evident from these facts that if we choose as our standard dose the smallest amount which will bring about a maximum rise, a drug much stronger than our standard will cause much the same rise but will, through its toxic action, cause to fall sooner than would a weaker preparation, and thus a strong preparation will appear weak instead of strong.

To avoid this tendency to toxic action it will be necessary to give a dose, of the preparation to be tested, so small that there is no danger of overstepping the bounds of normal physiological action however strong the specimen in hand. The use of so small a dose betrays us unfortunately from the Scylla of toxic action to the Charybdis of uncertain reaction. It is a well-known fact of physiology, that the stronger the stimulus the more nearly in accord are the results obtained on different individuals. This is particularly true of drug action. If a sixteenth of a grain of morphine be given to each of a series of persons, it will cause sleep in this person, nausea in that, wakefulness in a third, and perhaps headache in a fourth. If however several grains are given to the same persons, it will cause narcosis in all. The same difference in reaction to small doses of medicine is seen in the effect of blood-pressure-raising drugs on different individuals. For this reason it is necessary to give first to the animals on which the tests are being carried out, a dose of a standard preparation, and then to determine how much of the preparation to be tested is required to bring about the same rise. The elimination of most drugs is so slow as to render this method valueless. With the exception of such drugs as amyl
nitrite, which are eliminated within a few minutes, and adrenal principle, which is destroyed as rapidly, the effect of the first dose cannot, under the ordinary conditions of experiment, be allowed to pass off entirely before the next dose is administered, and there is for this reason a cumulative action, each dose adding to the effect of the previous one, and rendering a true comparison impossible.

We thus come by a process of exclusion to the third method, the determination of the amount of a drug required to cause death. This amount is ordinarily determined by injecting into a series of animals, progressively larger doses of the drug under consideration, and noting the smallest dose required to cause death. The method is therefore known as the minimal lethal (fatal) dose method. A large series of experiments show that by basing the dose on the weight of the animal, the activity of the preparation can be determined to within 10 per cent. That is to say, if a given dose is the smallest which will kill a given animal, eleven-tenths of this amount will kill almost any individual of the same species, and nine-tenths of this amount will hardly ever kill. This fact bears out what has been said above concerning the agreement in the effects of large doses.

Granting then that the method gives concordant results, can we be at all sure that the toxic power which is estimated in this way is in accord with the therapeutic activity of the preparation? The physiological action of these drugs, on which their therapeutic value depends, is mainly a stimulation of the heart, shown by more forcible contraction of its wall. The drugs kill either by inducing a state of constant contraction (death in systole) or by overworking the heart muscle to such an extent that it gives way to a more or less sudden exhaustion with relaxation (death in diastole). In either case, the effect is primarily due to stimulation of the heart, and thus varies in accord with the physiologic or therapeutic activity. In this connection it may be as well to mention that occasionally in mammals, respiration ceases before the heart has come to a standstill. This does not indicate any direct action of the drug on the respiratory centers, but is due to interference with the function of the medulla, dependent on the disturbance of its blood supply. The death is thus due to the stimulating action on the heart, however it may eventually occur. Granting then that the lethal-dose method is not only exact, but also determines the physiological activity, what animal is the best to use? It is often stated that as the drug acts on the medulla in mammals, as shown by respiration occasionally ceasing before the cardiac contractions, the drugs should be tested on frogs, in which it acts on the heart. As we have seen, the respiratory failure is really due to beginning cardiac exhaustion, and in reality there is no essential physiological difference between the action of the drugs on the frog and on the guinea pig. The action of digitalis is largely exerted on the cardiac ganglia. In the frog these ganglia are in the heart, as may be demonstrated by the continuance of contractions after the removal of
the organ from the body. In birds they are in the spinal cord, as is shown by the cardiac action continuing after the head is cut off. In mammals, however, the cardiac ganglia are in the base of the brain and any stimulus acting on these ganglia acts of course on the brain.

The frog is an unsatisfactory animal for the purpose of standardization, as its reaction to stimulation is markedly influenced by external surroundings, temperature, amount of moisture present in the cage, relation of time of injection to time of feeding, etc. The species of frog also makes a difference and, according to many authors, the time of year. Certain writers believe that season has of itself no influence, but that the differences found are dependent on different species being used, or on temperature. Although the uncertainty arising from these factors may be avoided by great care, there will be a difference in different lots of frogs, and it is recommended by those who use the frog method, that a standard preparation of each drug be kept on hand and that each fresh batch of frogs be studied as to their relation to the standard before they are used for the purpose of testing new preparations. This makes the standard dependent on the keeping properties of a stock galenical, and these are exceedingly uncertain in many drugs. Any deterioration will result in a lowering of the standard for all subsequent preparations. For these reasons it seems wiser to use some animal which shows no such variation, is always of the same species, can be easily obtained, and is large enough to allow accurate and easy calculation and measurement of doses. The guinea pig fulfills all of these requirements, and has therefore been selected by us for use in our experiments, moreover, as the guinea pig is very resistent to the action of alcohol, it is not necessary to evaporate alcoholic preparations to dryness before injecting them. The necessity for such evaporation when using frogs is of course well known.

It is a noteworthy fact, to which attention has often been directed, that the smaller animals require doses much larger in proportion of their weight. For instance, 0.75-Cc. tincture of digitalis which can be given safely to a 250-gram guinea pig, would correspond to 7.2 oz. to a 250-pound man, which would be far above a fatal dose. It has therefore been proposed that the dose should be based on the relative surfaces of the animals instead of on their weight. This would be the two-third power of the weight. (The square of the cube root). This would give a dose of little more than 1 oz. to a 150-pound man, which is about the largest dose which can be given safely. A series of experiments on guinea pigs of different weight, have shown that this argument does not apply to them. Comparing pigs of about 225 grams weight with others of 500 grams, we find that upwards of twice as much is required to kill the larger animals. This shows that for animals of the same species the dose should be in proportion to the weight and not in proportion to the surface area.

In doing the routine work of standardization, the guinea pigs are first
weighed, and then to one pig is given hypodermically the standard minimal lethal dose, to a second nine-tenths of this, and to a third eleven-tenths. If the drug is of proper strength, the two pigs receiving the larger doses will die, while the third will recover. This being the case, the drug or preparation may be passed as it is. If only the pig receiving eleven-tenths dies, the preparation is to be concentrated 10 per cent. If all three pigs die, a fresh pig is given eight-tenths of the standard dose and the dose is reduced by tenths until a pig lives. The preparation is then diluted accordingly. If all three pigs live, a fresh pig is given twelve-tenths, and others increasing doses until two die. The preparation is then concentrated to agree with the smallest amount received by a pig which is killed.

By this method it is possible to make preparations which are always within 10 per cent. of the same strength.

The standards on which I have decided after a large amount of work with preparations from different houses, are as follows:

**Dose Based on a 250 Gram Guinea Pig, and Proportioned to Weight if the Pig Used Does Not Weigh This.**

The most interesting point in connection with this table is the peculiar difference in the activity of the three preparations of squill. The alcoholic extract is about twice as strong as the acetic, or a little more, and the tincture about three times as active as the alcoholic extract; in proportion to drug strength.

We now turn to the consideration of the heart depressants. There are only three vegetable drugs in the Pharmacopoeia whose most important physiological action is a direct depression of the cardiac activity,—these being aconite, gelsemium and veratrum. Related to these in action is a group of drugs which exert their most marked action on the voluntary muscles, causing loss of tone in these, and killing by respiratory, rather than cardiac failure. This group includes physostigma, lobelia and conium. The drugs of the digitalis series, which kill by depression resulting from over-stimulation, show a very sharp line between their therapeutic and toxic doses. A dose slightly less than that which is required to cause death, causes only slight toxic phenomena. With the drugs of this class, on the contrary, the toxic symptoms are manifested even under the influence of comparatively small doses and these increase gradually until death.
is reached. For this reason, the dosage of these drugs is not as sharply defined as that of the drugs previously considered, and it is necessary, in making a standard for these drugs, to arbitrarily fix a period of time within which the animal must die, if the drug is to be considered up to standard. This period has been fixed as three hours, as we have found that ordinarily a dose which will eventually prove fatal will do so within this time.

The heart depressants differ from the drugs of the digitalis series in another respect, each of them producing evident effects when given in sublethal doses. Aconite causes in many cases, nausea, which is shown in the guinea pig by violent retching. As far as our observations are concerned, this animal never vomits. The irritant effect is also shown by the tendency of this drug to cause diarrhoea.

Gelsemium is likely to cause convulsions and these are frequently followed by paralysis, even in cases in which the animal eventually recovers. The guinea pig poisoned with gelsemium lies on the side, moving the legs feebly from time to time and breathing irregularly, and frequently only at long intervals. This paralysis may not come on until an hour or so after the administration of the drug and in this case, recovery is likely to take place. If the paralysis occurs within twenty minutes of the time the drug is administered, the dose will generally prove fatal.

Veratrum stands between aconite and gelsemium in regard to these phenomena, causing convulsion less frequently than the latter, but being very likely to cause paralysis. Retching and diarrhoea, although not so common as with aconite, are frequently seen. It might be mentioned in this connection that, of the drugs spoken of in the previous article, apocynum frequently causes paralysis, even in animals which eventually recover, and squill and convallaria often cause convulsions. Digitalis is much freer from these sublethal toxic phenomena.

The drugs which have been mentioned as causing death by failure of the respiration can all be standardized by chemical means, as their activity is largely dependent upon their alkaloidal content, although aconite, gelsemium and veratrum contain alkaloids on which their activity depends, their physiological strength does not necessarily nor invariably vary in accordance with their total alkaloidal content. The physiological activity of aconite is mainly due to the aconitine which it contains, but this alkaloid contains in chemical combination a methyl and a benzoyl group, either of which may be split off during the handling of the drug and the loss of which renders the aconitine inactive, while still permitting it to respond to the chemical reactions of an alkaloid. This is particularly prone to occur on long standing of its preparations. Veratrum contains, in addition to veratrine, a series of alkaloids, among which may be mentioned protoveratrine, veratroidine and protoveratridine, which are almost entirely inactive, but which cannot be easily distinguished chemically from
the active alkaloids. Gelsemium contains two alkaloids, gelsemine and gelseminine, the former of which has practically no effect on mammals, but cannot well be distinguished by any chemical assay process. On account of the possibility, therefore, of obtaining misleading results from chemical assay alone, we are reduced to the necessity of substantiating such assays by physiological means. Conium, physostigma and lobelia all contain alkaloids upon which their pharmacologic and therapeutic activity depends, and the amount of which gives a direct indication of the therapeutic activity of the product. It is therefore not considered necessary to standardize these products physiologically.

After a large number of experiments extending over several months, the following standards have been adopted for the three drugs first mentioned. In each case the amount mentioned is injected subcutaneously into a guinea-pig, and other pigs are given respectively \( \frac{9}{10} \) and \( \frac{11}{16} \) of the standard dose. If all three of these doses prove fatal, a smaller dose is given to a fresh pig; if none prove fatal, a larger dose is given to a fresh pig. If the dose given in the table proves fatal within three hours, and the pig receiving \( \frac{9}{10} \) of this lives longer than this period, the drug is considered to be of standard quality. The doses given in the table are based on 250-gram pigs, and in case the pig weighs more or less than this amount, are made proportionate to its weight. The dosage is given in grams of the drug and extract and in cubic centimeters of the liquid preparation.

Feeling that perhaps the standard lethal doses of the drugs referred to in this paper might be more clearly understood if they were stated in a manner similar to that in use in describing the strength of bacterial toxins, that is, by stating the number of units contained in a cubic centimeter of a standard preparation, we suggest the following system, namely, that the unit in this case be the amount required to kill one gram of animal (guinea pig). By this method of calculation we have prepared the following table:

Of the drugs tabulated in the preceding portion of this communication only the following are sufficiently accurately provided with chemical assay processes, to enable us to make comparisons:

Digitalis,aconite root, aconite leaf, gelsemium, veratrum.

**Digitalis:** Attention is first called to the article by Reed and Vanderklee on the standardization of digitalis preparations, published in the March, 1908 number of the American Journal of Pharmacy. There on page 119 is given a table showing the relationship between chemical assay for digitoxin and physiologic assay based upon lethal dose for guinea pigs, for nine preparations. During the past year, the results as shown in the following table indicate that the minimum lethal doses as obtained by Dr. Reed two years ago were slightly smaller than those obtained by Dr. Githens during the past year, when compared with the results obtained by chemical assay as described in the article mentioned above.

Average ................................................................. 0.03061

A study of the table of March, 1908 shows that an assay of about 0.025 Gm. digitoxin per 100 Cc. corresponded closely with a lethal dosage for 240-Gm. guinea pigs of about 1 Cc. A careful scrutiny of the above results shows not quite so uniform an agreement, but on the whole, a minimum lethal dose of 1 Cc. corresponds fairly closely with an assay of 0.030 Gm. digitoxin per 100 Cc. The third column, consisting of figures representing the purity of the crystalline digitoxin obtained depends
largely on the manipulation of the bulky lead subacetate and sodium phosphate precipitates (see Amer. Jour. Ph. 1908, p. 118). A centrifuge is now being installed in our laboratory suitable for sedimenting these preparations, and by its use, it is hoped that a higher degree of purity of the separated digitoxin will be obtained, insuring results still more nearly concordant with physiologic assay.

**Aconite Root and Leaf.**—The chemical assay methods employed for all aconite preparations in the following table were essentially those of the U. S. P.

Average 0.444

A survey of the above table shows far less concordance between chemical assay and lethal dose than in the case of digitalis. The agreement is fairly close in the case of the tinctures and of the fluidextract of leaf, but the two fluidextracts of root possess a degree of toxicity about 25 per cent. greater than should have been expected from the chemical assay. A continuation of the collection of data will throw additional light on this peculiar observation.

**Gelsemium.**—A comparison of the results of chemical assay for total alkaloids in gelsemium with its minimum lethal dose, was first undertaken at the suggestion of Prof. L. E. Sayre, who describes the results first obtained on page 855 of the 1908 Proceedings of the American Pharmaceutical Association. Attention is also directed to the reported discussion on Prof. Sayre’s paper on pages 851–8 of this volume. The following table shows the results obtained since that time, the chemical assay method used being that of Webster as described by Sayre in the article mentioned above:
STANDARDIZATION OF CARDIAC STIMULANTS AND DEPRESSANTS.

Average ........................................................................ 0.375
Average on Fluid and Solid Extracts alone ....................... 0.437

This table serves to demonstrate the necessity for physiologic control of the chemical assay for gelsemium and the worthlessness of the latter unless accompanied and checked by the physiologic test. Just contrary to the results obtained with aconite, the tinctures of gelsemium are much more toxic than the fluidextracts, on the basis of equivalent amounts of total alkaloid. This is probably due to a higher proportion of highly active gelseminine being taken up by the percolation which occurs in the preparation of the tincture.

**Veratrum.**—The chemical results, expressing total alkaloids, in the following tables were obtained by the following method:

The fluidextract, 10 Cc., or the tincture, 100 Cc., is evaporated on purified oak sawdust, and the dried mixture macerated with a mixture of ether 80 Cc., chloroform 20 Cc., and ammonia water 10 per cent. 10 Cc. An aliquot part of the ethereal extract is shaken out with 5 per cent. acetic acid, rendered alkaline with ammonia, shaken out with chloroform, evaporated, dried, and weighed.

In the case of the solid extract, two to three grams are dissolved in 50 per cent. alcohol, filtered onto purified oak sawdust and finished like the fluidextract and tincture.

Average ........................................................................ 0.115

Except for No. 6 in the above table, the lethal dose of which is abnor-
minally high in comparison with the chemical assay, the activity of preparations of veratrum seems to agree quite closely with the percentage of total alkaloids. The chemical assay of veratrum appears therefore to possess undoubted value.

It is the intention of the authors to continue the tabulation of comparative results of physiologic and chemical assay of these drugs, as well as to start similar series of comparisons on conium, physostigma and lobelia.

The Chairman: There are several papers along the same line. We will first have them read, and then discussed. The next paper is on "The Variability of Digitalis," by Dr. Worth Hale.

Dr. Hale here read his paper as follows:

THE VARIABILITY OF DIGITALIS.

BY WORTH HALE, M.D., ASSISTANT PHARMACOLOGIST, HYGIENIC LABORATORY, U. S. P. H. AND M. H. S.

So much has been written concerning the variability of digitalis that it would seem unnecessary to write further upon the subject. However, additional facts develop from time to time so that many of the points at issue are by no means definitely settled.

The purpose of this short paper is to point out certain experimental evidences, part of which support and part of which oppose certain factors which, because of much repetition in the literature, have seemed to be definitely established, and to propose a remedy by which most of them may be ignored.

Since whatever conclusions to be drawn from a series of experiments depend for their value upon the accuracy of the method used, the method of experimental procedure will be briefly described. As an assay method for digitalis and other allied drugs the chemical method does not seem to be as accurate or reliable as biological methods. The method provisionally adopted at this laboratory was chosen because it appeared to offer certain advantages over others in common use and moreover to be simple and easily carried out.

Healthy frogs of the same species are injected with the preparation under consideration. The animal is kept at a constant temperature of 22° to 23° C. for one hour, at the end of which time the brain and cord is destroyed and the thorax opened to note the condition of the heart. As an end reaction the ventricle must have just stopped in permanent systole.

To test the accuracy of the method eighteen unknowns, consisting of weighed amounts of the so-called pure principles of digitalis, strophanthus, and convallaria dissolved in 25 per cent. alcohol were assayed. Upon comparison of the values obtained by the use of frogs with the record of the amounts by weight it was found that the error varied from zero to 10
per cent., but on the average 3.9 per cent. for the whole series. The great value of a method as accurate as this is made plain when it is remembered that digitalis as obtained on the open market has been thus shown to vary as much as 400 per cent. in activity.

Having thus established the approximate accuracy of the method for quantitative work, a number of the commonly cited causes of the variability in digitalis and its preparations were taken up.

It has been repeatedly stated that only second-year digitalis leaves should be used, and in recognition of this the Pharmacopoeia prescribes leaves of the second year's growth. Focke, a German investigator, reported, however, when compared with digitalis leaves of the second year gathered at the time of seeding that first-year leaves were about 20 per cent. more active, although at time of flowering the order was reversed. Hart in England reported the assay of one sample of first-year leaves, which gave a value also about 20 per cent. higher than second-year leaves, but which were gathered at the time of flowering.

My own experience is with three lots of first-year leaves, all of which were garden-grown. One was grown at Madison, Wisconsin in 1908, and two in the Government drug garden at Arlington, Virginia, one of the 1907 crop, the other of the 1909. The leaves were powdered to number 60 powder and then made up into tinctures according to the U. S. P. VIII. The results of their assay were as follows in terms of heart units per Cc. (By heart unit is meant the amount of the preparation per gram weight of frog to produce the end reaction). Arlington, 1907, 200 heart units; Arlington, 1909, 200 heart units; Wisconsin, 1908, 182 heart units. A tincture made up from Allen's English leaves at the same time and in as nearly the same manner as possible contained 133 heart units per Cc., or in terms of per cent. the first-year leaves were 50, 50 and 37 per cent. stronger than select English leaves of the second year's growth. As a further proof of the high activity of these lots of first year leaves it is of interest to note that in all my experience with assay work only one other tincture, presumably made from second-year leaves showed as high values as these.

In connection with these assays a further interesting fact is to be noted, namely that this high value was given by leaves grown in gardens. The often repeated statement that wild growing plants furnish leaves of the higher potency probably is true in many instances but it seems doubtful that this fact alone has much to do with high activity and that to specify either second-year plants or leaves from wild growing plants in the Pharmacopoeia will decrease the variability factor or increase the potency of the preparations made from them.

A point often made, and which would seem to have considerable importance in securing digitalis leaves of a high value, relates to the manner of drying. Hamilton as early as 1807 warned physicians against the use of
improperly dried leaves and since then many similar reports based either on clinical or experimental knowledge have been made. Focke especially lays much stress on this point not only as a means of securing preparations of high activity, but what is equally important, of delaying their deterioration with age. As a result of his work he recommends that the leaves should be so dried as to contain not more than 1.5 per cent. moisture and to maintain this condition that they should be stored in air-tight glass containers.

My own experience regarding this point is by no means extensive nor is it absolute. However a number of facts have developed to show that leaves as ordinarily dried and containing approximately 5 to 8 per cent. of moisture may maintain a high potency for some time. Thus an assay of digitalis leaves at least 8 years old and entirely open to the influence of atmospheric conditions had as marked activity as fresh English leaves; 1907 first year leaves examined in 1910 were as active as first year leaves of the 1909 crop. Both were only ordinarily dried and were stored in cloth bags in a climate that is very humid. Nevertheless and possibly further attesting the potency of first year leaves, these were of exceptionally high activity. 1908 English leaves, containing 7.8 per cent. moisture were examined 1909 and again a year later showing the same activity in each case. Thus there does not seem to be necessarily any marked deterioration because of ordinary amounts of moisture. But if sufficient moisture be added as in one instance to cause moulding, the decrease in activity in nine months was about 90 per cent. In conclusion therefore it seems probable that while careful and prompt drying is of some importance it is not at all essential to reduce the moisture content to 1.5 per cent.

In this connection the use of heat as an aid to the drying process is of importance. Several small lots of powdered digitalis were submitted to temperatures ranging from 80° to 140° C. for two hours. These were then made up into official tinctures and assayed. Up to 120° C. no deterioration was evident; at 140° C., however, the preparation was approximately 60 per cent. weaker than the normal, containing only 71 as compared with 125 heart units per Cc., the value of the normal, as the average of the series of experiments.

Preparations of Digitalis:—The finished digitalis product has been shown to vary equally in strength with the crude drug—that is, about 400 per cent.—Several reasons are offered in explanation of this fact although by far the most important is the variation in the crude drug itself. However, from my limited experience I wish to emphasize the point advanced by Vanderkleed and Bernegau in 1908, namely, that to use an assayed crude drug does not necessarily insure a uniform finished product. On that account the record of the assays of the crude drug in the first part of this paper are to be regarded as only relatively absolute although the
preparations, the tinctures, were prepared in as nearly as possible the same way at the same time to make more certain equable conditions. Thus tinctures prepared from the same leaves gave values in the inverse ratio of 8, 7 and 12*; another series, 7 and 9.

Differences in percolation are responsible undoubtedly for the fact that the fluidextracts of digitalis assay not 10 times but on the average only 5 times stronger than the tincture. Fluidextracts and tinctures made from the same leaves in several series of percolations gave values in the ratio of approximately 1 to 3 and not as might be expected a ratio of 1 to 10.

In this connection and based partly on this evidence I wish again to enter a protest against the fluidextract of digitalis. So far as I can determine it is used only in preparing solutions said to represent the official tincture or what is more absurd the official infusion but which most certainly do not correspond to them either in strength or necessarily in character.

Although differences in manipulation may cause considerable variation in the finished product the further factor of subsequent deterioration is also to be considered. This was emphasized by Dr. Houghton in a paper before the Association a year ago. My own experience though less extensive is largely confirmatory. I have found however that while certain preparations deteriorate with age others do not seem to do so, at least not so rapidly. Thus two official fluidextracts examined in 1908 and again in 1909 showed the same activity. On the other hand three preparations made up according to special formulas showed a decrease in activity; one of 25 per cent., one 60 per cent., and one more than 100 per cent. A fourth preparation made according to a special formula examined in 1908 only was entirely devoid of a digitalis action. But it is not urged, in spite of this evidence, that digitalis preparations made up according to special formulas invariably deteriorate more rapidly than the official preparations. It only makes the use of such preparations questionable until thorough tests of their keeping qualities under the ordinary conditions found in pharmacies have been made.

Further evidence of slight deterioration in certain preparations is afforded by the results of assays of three tinctures made at the German Hospital, Philadelphia. One of these was made from English leaves according to the U. S. P. in 1908, the other two in 1902, one from English and one from German leaves. All showed about the average potency of digitalis tinctures, the 1908 sample made up with 50 per cent. alcohol as the menstruum assaying 143 heart units per Cc., the 1902 preparation made from English leaves according to the International standard with 70 per cent. alcohol as menstruum also assaying 143 heart units per Cc., the

* No reason for the low assay value can be given but it was undoubtedly due to faulty percolation.
third made from the German leaves according to the International standard with 70 per cent. alcohol assaying 117 heart units per Cc.

These results show therefore either a very high original potency for the preparations made according to the International standard or what seems more likely deteriorated very little during the years since their preparation in 1902 owing to the higher percentage of alcohol used.

**CONCLUSIONS.**

1. First year leaves are not necessarily weaker than second year leaves and might be used in preparing assayed digitalis preparations.

2. There is not necessarily any difference in the activity of wild and garden grown leaves.

3. Excessive drying is not essential in preventing deterioration of leaves although prompt and thorough drying to less than 10 per cent. moisture or perhaps even somewhat more completely is essential.

4. The assay of the crude drug does not necessarily insure a uniform finished product.

6. Great variability in the keeping qualities of preparations is to be noted, but the deterioration from age seems to be very slight if 70 per cent. alcohol is used.

As a remedy for all the variations in digitalis the physiological assay of all official preparations to a definite strength and by a definite official method is proposed. The method to be adopted might be one of several, but on account of its simplicity and accuracy essentially the same method used by Famulener and Lyons* is offered for general adoption. *This with certain modifications, may be as follows:*

1. The animals used should be frogs (Rana pipiens), weighing between 15 and 35 grams to be kept until used in storage tanks at a temperature of 10° to 15° Centigrade.

2. When used they should be brought to the operating room, injected through the mouth into the abdominal lymph sac with definite amounts of the drug per gram of body weight and placed in jars or cages kept at a temperature of 22° to 25°C.

3. At the end of one hour the frog should be pithed, the thorax opened and the condition of the heart noted.

4. As an end reaction the ventricle should have just come to a permanent systole, a reaction which is easily determined by injecting a series of frogs with such doses that the heart will be beating in part and in permanent systole in others. A unit is proposed to show variations in activity in direct ratio to the strength of the preparation; the unit to be that amount of drug in Cc. per gram of body weight to bring on the end result and the results tabulated in units per one Cc. of the preparation.

THE BIOLOGICAL STANDARDIZATION OF DRUGS.

This paper was read by Dr. Hatcher, who accompanied his remarks by blackboard illustration.

THE BIOLOGICAL STANDARDIZATION OF DRUGS.

BY ROBERT A. HATCHER AND J. G. BRODY.

This comprehensive title was chosen by one of us some months ago with the intention of presenting brief outlines of a number of methods of biological standardization which retail pharmacists would find available.

Since then we have been devoting most of the time at our disposal for the purpose to the study of one group of drugs, and we shall therefore limit the scope of the paper to a single method, and a consideration of some of the drugs for which the method is adapted.

Crawford (Am. J. Pharm., vol. 80, 1908, p. 321) has given an excellent review of a number of the more important methods of biological assay. He says: "The group of digitalis, strophanthus, and squill is the most important one which we as physicians have to use, and it earnestly demands standardizing." He quotes Naunyn as saying that he would not care to be a physician without digitalis. He also quotes Dixon as saying: "For my part I unhesitatingly express the belief that many hundreds of patients die annually from digitalis and allies not possessing the virtues required of them." To the foregoing we would add that we are equally convinced that the want of precise methods of dosage is responsible for many cases of poisoning with digitalis, and it is with this group of drugs that we have been engaged for the most part.

We are aware that many will raise the objection that the details of biological assays are of little more than theoretical importance to the retail pharmacist because he is unable to conduct these operations. We believe that the progressive pharmacist must be prepared to make the simple biological tests at least, if he is to pretend to keep pace with the progress of his profession, and it is our purpose to outline the technic of our method, which is so simple that it may be mastered by the retail pharmacist, and conducted with the apparatus which he has at hand.

H. C. Wood, Jr., has recently sought to convey the impression that it is hopeless to expect any degree of precision by means of the test on animals even when it is conducted by the trained pharmacologist. Wood says: "And first I shall speak of its limitations. We sometimes read of the physiological test being used as a control of the chemical assay. To attempt to corroborate the findings of the chemist by a test on the living animal is about as sensible as it would be for a navigator to regulate his chronometer by an Ingersoll watch; the relative accuracy of the chemical and physiological assay is about the same as that of the $200 chronometer and the dollar watch."
To this statement we wish to enter certain exceptions.

Method.—The method of standardization which we have chosen for the digitalis group and some other drugs consists in determining the minimal fatal dose per Kg. of cat when the drug is injected slowly into the femoral vein, the standard chosen for the digitalis group being the cat unit.

The cat unit may be defined most accurately perhaps, as the amount of crystalline ouabain* which is fatal within about ninety minutes to a kilogramme of cat when the drug is injected slowly and almost continuously into the femoral vein. A cat unit is equal to almost precisely 0.1 Mg. of crystalline ouabain, or one ten-millionth of the weight of the animal.

We would prefer this definition of the cat unit rather than that which would embrace any digitalis body required to produce a similar effect within the same period of time when used in this way. The reasons for this will be apparent from the discussion of the method.

When crystalline ouabain, amorphous strophanthin, or a preparation of strophanthus is to be tested, it is only necessary to inject the solution from a syringe or burette into the femoral vein until the animal begins to show toxic symptoms. The injection is then interrupted, or continued more slowly until the unmistakable signs of approaching death are seen. These signs are so typical that one is rarely mistaken concerning them. They consist in irregularity of the heart, difficult respiration, convulsions, and frequently a peculiar cry, after which recovery is extremely rare. If death does not occur in a few minutes the injection is continued with extreme caution.

Other members of the digitalis group may be tested in the same way, but the results will be somewhat too high as a rule, and in that case the necessary correction, usually amounting to about 20 per cent., may be made, or the assay may be made more accurately by a modification of the technic. Somewhat more uniform results are obtained if about 75 per cent. of the total amount of the digitalis body is injected in the first fifteen minutes and the remainder in the following hour. These results will still be too high, and we have therefore devised a modification of the method of estimating some of the other digitalis bodies which gives results which we believe to be nearly as accurate as those obtained with crystalline ouabain itself.

It might be better to explain the reason for this modification first, but for convenience the discussion will be given later.

Just as the analytical chemist may find it desirable to determine the alkalinity of a liquid by adding an excess of acid and titrating back with an alkali, so we have been able to obtain more accurate results in some cases when we inject a measured amount of the digitalis body (tincture or infusion of digitalis, or digitoxin) in the first period of about ten minutes, * The older term ouabain is to be preferred to that of crystalline strophanthin, which has lead to much confusion.
and after an interval of twenty minutes continue the injection, substituting a solution of crystalline ouabain for that of the digitalis body under examination until the death of the animal, or until the toxic symptoms appear. Naturally, we assured ourselves that ouabain was capable of replacing the other digitalis bodies before we adopted this method.

The difference between the amount of crystalline ouabain actually used to complete the assay and 0.1 Mg. per Kg. of animal (the amount which would have been required in the absence of the digitalis body), represents the activity of the digitalis used.

The following example will illustrate the mode of computing the activity of the digitalis body tested: A tincture representing 70 mgs. of digitalis per kg. of cat was injected into the femoral vein and after twenty minutes the injection of a solution of ouabain was begun. The animal died with the typical symptoms of digitalis poisoning when 0.00142 mg. of the crystalline ouabain per kg. had been injected. The difference between 0.0142 mg. and 0.1 mg. (which would have been required had the ouabain been used alone) is 0.0858 mg. or 85.8 per cent. of a cat unit, hence 70 mgs. of digitalis equals one cat unit. A duplicate experiment gave 18.8 mgs. of the digitalis. That the results obtained by the modified technic are more accurate than those with the continuous injection of the digitalis alone is shown by a comparison of the results of the following experiments intended to fix the minimal lethal dose of digitalis by the vein with those given in Table III.

2 /24/10. Male cat, Wt. 3.65 kgs.
10.30 A. M. Injected 0.085 Gm. digitalis per kg. by vein at once.
10.45 A. M. Emesis. Cat lived over 7 hours, but died during the night.

4 /9/10. Female cat, Wt. 2.02 kgs.
11.40 A. M. Injected 0.080 Gm. per kg. by vein at once.
12.02 A. M. Emesis. (Repeated emesis.)

4/11/10. Cat weighs 1.68 kgs., having lost 0.34 kg. in weight.
9.42 A. M. Injected 0.075 Gm. digitalis per kg. by vein at once.
9.58 A. M. Death occurred. (Cumulation.)

We have tested the following substances by intravenous injection into the cat: Crystalline ouabain, amorphous strophanthin, strophanthus seed, tincture of strophanthus, digitalis, tincture of digitalis, infusion of digitalis, digitoxin, digitalinum verum, digitalein, adonidin, digalen, amorphous digitoxin so-called, digipuratum, all belonging to the digitalis group, and German digitalin which does act like digitalis when injected in this way, since it consists largely of digitonin which causes a sharp fall in the blood pressure when injected into the vein. We examined digitonin and sparteine also, neither of them giving the digitalis action. Strychnine gave fairly uniform results, but the method requires careful control. Nicotine,
physostigmine, and aconitine did not give concordant results in the experiments we made, and we have not been able to determine whether it is possible to modify the technic so as to make it available for those bodies or not.

The estimations in the table were made by the continuous injection of the various bodies mentioned except in the case of digitoxin and the digitalis leaf, and it is quite possible that corrections will have to be made for some of these when crystalline ouabain is used to complete the injection. Attention is called to the similarity of the results reported to those obtained by Worth Hale in comparing crystalline digitoxin with the amorphous so-called, (*J. Am. Med. Assn.*, v. 54, p. 35), but we believe that the method reported here has the advantage of greater accuracy and ease with which it may be followed, and of great economy in time.

The values in Table III were obtained by the injection of digitalis alone (cf. Table II) A. represents a tincture obtained from leaf ground for percolation by Gilpin, Langdon & Co., in Oct., 1906. B. was from a specimen obtained from the same firm in April, 1910, and was said to have been obtained as recently as possible. D. was from an English leaf obtained at the same time as the German just mentioned. It was said to be from a carefully collected and treated cultivated leaf.

C. had had 100 Mgs. of the same per rectum 3 hours previously.

D. were labeled Mixt. A. and B., and the strength of these were unknown to the operator, Dr. Brody. In the first of these two experiments 2.73 Cc. per kg. were used, the cat weighed 1.65 kgs., hence 4.5 Cc. were injected; in the second 3.18 Cc. per kg. were used for a cat weighing 2.22 kg., a total of 7.05 Cc. The first solution represents 125 Mg. in 3 Cc., and 3.5 Cc. of the second represents a like amount.

Four estimations of digitalinum verum were made. 1.50; 1.52; 1.56, and 1.80 Mgs. respectively were found to be equal to 1 cat unit.

Digitalinum verum and digitoxin being insoluble in water, alcoholic solutions were employed.

Four estimations of digitalein were also made, the equivalents of a cat unit being 2.89; 2.90; 2.98, and 4.50 Mgs. respectively. Digitalein being very soluble in water, is used conveniently in this way.

Two lactating animals were given large amounts of strophanthus in one case, and digitalis in the other. The first took 217 Mgs. of digitalis per kg. of weight, which is more than twice the amount of this specimen usually required and the second took two and one-third times as much strophanthus as other cats of the same weight. These are the only two instances in which an animal required anything like so much of these two drugs. We are unable to state whether this is a coincidence or whether
lactating animals are habitually tolerant toward the drugs of this group. We hope to be able to decide this point in the near future.

Three experiments were made with impure adonidin. The first animal received more than 6 Mgs. of the drug per Kg. of weight. We had little idea of the activity of the specimen and injected it much more rapidly than in the second and third experiments, hence the excess over that actually required was much greater. This experiment should be disregarded in the calculations. The second and third animals received 2.86 and 3.12 Mgs. per Kg. respectively.

The results obtained with German digitalin require an explanation. German digitalin is wholly unsuited for estimation by intravenous injection, its true digitalis action being much less than that indicated by the figures in the table, death being due mainly to the digitonin of which it is chiefly composed. German digitalin probably has no place in digitalis therapy.

When the official preparations of digitalis, such as the tincture, are diluted with water, a precipitate occurs, indicated by a faint opalescence, and in our earlier experiments we were unable to get uniform results when these diluted liquids were injected over a period of an hour or more. The injection of a large amount of alcohol is not permissible, and the use of concentrated preparations precludes the same degree of accuracy that is possible with the more dilute liquids. These objections are overcome, in part, by the combined method, in which ouabain is used to complete the estimation.

We have never seen any embarrassment of the respiration beyond some increase in the rate until the heart stopped. The immediate signs of asphyxia with excessive efforts at respiration showed that the respiratory center was still intact. Furthermore, those drugs which kill by paralysis of the respiratory center, usually give very variable results when used in this way. Strychnine is an exception, but there are many factors involved in the rapid action of strychnine, and it is quite possible that the sudden death following the intravenous injection is not due to its direct effects on the respiratory center alone. The fact that the heart stops after all of the digitalis bodies before the respiration is seriously impaired is the strongest answer we can make to the contention of Edmunds and Hale (Hygienic Laboratory, Bulletin No. 48, 1908), that methods which employ as a standard the minimum lethal dose for the higher animals are not applicable to the physiological assay of the digitalis series.

It is hardly necessary to state that it is a matter of vital importance that a standard shall be found for all the digitalis bodies in which the relative activity of the different members on the human heart may be expressed.

Hale found between 7 and 8 Mgs. of digitoxin per Kg. of frog, and 600 Mgs. of digipuratum per Kg. (J. Am. Med. Assn., v. 54, p. 129) necessary to cause systolic standstill in an hour. This is sixteen times the amount of digitoxin, and eight times the amount of digipuratum, required.
per kilo for the cat's heart in our experiments. On the other hand, we have found that less than twice as much strophanthus is required per kilo of frog as for the cat.

The following figures expressed in milligrammes per Kg. of frog were obtained by Famulener and Lyons (Proc. Am. Ph. Assn., 1902, p. 415). Digitalis leaf, 675; digitoxin, 8.7: strophanthus (5 per cent. tincture), 5.625; strophanthin, 0.5 (c. f. Table 1); adonidin 4. They state in their conclusions: Determinations of the relative strengths of different samples of the same drug may be made with precision sufficient for practical purposes by physiological experiments on animals, but, as might be expected, the relative medicinal strength of different drugs cannot be correctly inferred from the observation of a single symptom produced in an animal like the frog. They found differences of less than ten per cent. in duplicate experiments.

A further disadvantage in the use of the frog is due to the differences in the rate of absorption of the different digitalis bodies. Even such closely related bodies as amorphous and crystalline strophanthin differing markedly in this respect. Famulener and Lyons have also called attention to this objection.

We have attempted to compare the results which those authors obtained when working with the frog with those obtained by ourselves with the cat but the differences are evidently due to differences in the animals and not to the limits of error.

Focke (Pharm. Zeitung, vol. 54, No. 68) says that after further consideration of the subject he believes that it is not feasible to accustom physicians to thinking and calculating the strength of digitalis preparations in frog units.

There are many reasons for believing that the action of the digitalis bodies on the cat’s heart is a better index than that on the frog’s of their effect on the human heart. Man absorbs strophanthin much as the cat and dog do, and the effects are much the same. Koppe's experiment in which 2 Mgs. of digitoxin taken in dilute alcohol caused serious symptoms, shows the possibility of rapid absorption and unusual action; on the other hand, we know of instances in which 2 Mgs. of crystalline ouabain have been administered intravenously without causing ill effects, though that is 25 per cent. of the theoretically fatal dose.

The cat is the least resistant to strophanthin and ouabain of all the animals which we have examined, but the rat and mouse alone, so far as our experience goes, are very resistant. There are marked differences in the subcutaneous and intravenous doses for the rabbit and some other animals, but not for the cat and the dog.

The various digitalis bodies are the subject of clinical investigation at the present time in certain of the hospitals in New York, with the object of comparing their quantitative therapeutic action in connection with the
results on the cat's heart, as shown by the experiments which we are conducting.

Naturally, minimal doses are being employed, but the comparative activity of crystalline ouabain and strophanthin even in the doses which have been recommended, seem to explain why positively brilliant results have followed occasionally the intravenous use of these substances.

We believe that the cat unit offers an easy means of computing the therapeutic dose of the various digitalis bodies when these are to be administered intramuscularly or by vein, but the rate of absorption from the alimentary canal must be determined before the oral use of these can furnish us reliable results.

That cumulation does occur with certain of these substances must be admitted, or, what amounts to nearly the same thing, the drug is not excreted or destroyed so readily in some cases as in others.

Strophanthin and ouabain may be repeated more frequently than digitalis, our incomplete investigations leading us to believe that the action of digitalis is far more persistent than is generally supposed.

We believe the outlook is more encouraging now than it has been at any time in the past for putting the therapeutics of digitalis upon a rational basis, but it must be admitted that we have no means at present of securing any degree of uniformity of action after the oral administration of these bodies, though it is not hopeless to look for one which will be absorbed readily from the alimentary canal, and we are endeavoring to find such a member of the group.

DISCUSSION.

The Choice of the Animal.—There are several reasons which influenced us to use the cat. These are in the order of their importance: Accuracy afforded, facility with which they may be obtained, ease with which they may be handled (contrary to common opinion), cheapness, and the fact that their use does not effect the sensibilities of the sentimental portion of the community to the same extent that the employment of the dog does.

The Use of Ouabain to Complete the Reaction after Digitalis.—It is commonly stated that digitalis acts slowly, thus Sollman, Text-book of Pharmacology, 2nd ed., p. 488, says: "The action of the digitalis group is peculiar, in that it cannot be secured at once, unless toxic doses are given intravenously. If this is done, the animal goes through all the stages; but even in this case, several hours are required until death occurs, no matter how much of the drug is given."

The latter part of this statement does not apply to the cat, nor does it apply to strophanthin so far as I am aware; nevertheless, it is true that moderate * doses of digitalis act much more slowly on the cat's heart than

---

* Massive doses of digitalis may cause death in 60 seconds, or about half the time re-
crystalline ouabain does, hence the interval that occurs between the injection of the minimal fatal dose and the death of the animal is longer with digitalis than it is with ouabain, and a greater excess of the digitalis will be injected during that interval. If approximately fifty per cent. of the fatal dose of digitalis is injected into the vein and twenty minutes are allowed to elapse and the injection is then continued using one part of crystalline ouabain in one hundred thousand parts of physiological salt solution, the end reaction is almost as sharp as with ouabain alone, the interval appearing to suffice for the digitalis to exert almost its full action on the heart.

The extraordinary uniformity* of the action obtainable with ouabain and other digitalis bodies on the cat's heart calls for some comment. We have been inclined to think that this might be explained by the absence of racial peculiarities, due to the nocturnal habits of the cat whereby cross breeding is almost universal. We are endeavoring to explain this uniformity, and while we believe there is a deeper significance than the one just suggested, we are not prepared to go deeply into a discussion of this phase of the question at present.

The fact that crystalline ouabain is capable of replacing amorphous strophanthin, as well as the digitalis bodies found in the leaf, as far as the direct action on the heart is concerned, lends support to the suggestion made by Schmiedeberg many years ago that all the members of the digitalis group depend on a similar nucleus for their action.

The use of this method of biological assaying and its remarkable accuracy have led us into the investigation of some problems which we wish to mention at this time, though they have no immediate connection with the subject of the paper. We are employing it to show the degree of absorption which occurs after the oral administration of the various members of this group. The results show that absorption is exceedingly irregular with all of them which we have tested. By this means we have also found that the tincture of digitalis represents the activity of the leaf fully, the marc left after the preparation of the tincture from a specimen of the German digitalis in one case, and from the English in another, being inert. The same may be said of the infusion, at least a 1 per cent. infusion required by the largest doses of crystalline ouabain. We believe that this extraordinary rapidity of action of digitalis is attributable largely to digitalein, which also acts rapidly.

* Since writing the preceding statement, which was based on a very large number of experiments covering a period of several years, we have found a number of cats which tolerated doses up till nearly fifty per cent. more than that stated. We are unable as yet to explain this. As previously stated, the only ones which succumb to doses below the standard are the excessively fat. The later observations do not prevent the use of this method of standardization, but a somewhat larger number of observations are necessary than would be otherwise.
showed the same activity as the tincture diluted to the same strength, and, as just stated, this fully represented the leaf. We have also found in one case that a carefully prepared tincture of strophanthus, made according to the pharmacopoeial process, represented only about two-thirds of the total activity of the seed, despite the fact that percolation had been continued for one week. The greater part of the strophanthin which is extracted is removed during the first part of the percolation, a part of the strophanthin, or some related body, being removed slowly by percolation. The total active principles of the seed may be removed completely, so far as we have been able to determine, by infusing the finely powdered seed for one hour on a boiling water bath.*

The foregoing suggests a number of ways in which the biologic test may be utilized by the retail pharmacist.

Several interesting points are raised by the results with strophanthus recorded in Table I. A specimen of *Strophanthus hispidus* was examined and the tincture and the infusion gave concordant results indicating that 3.5 Mgs. equaled 1 cat unit. A specimen of the Kombé showed exactly half the activity of the hispidus, 7 Mgs. being found to be equal to a cat unit, a tincture and an infusion being likewise examined. Subsequently an authentic specimen of each, obtained from Professor Rusby, was examined, the seed being finely powdered and exhausted by heating on a boiling water-bath for an hour. The ratio of activity of the infusions was the same as that just mentioned, but both infusions were much stronger than we had anticipated they would be, and 1.5 Mg. of the hispidus and 3 Mgs. of the Kombé were found to be equal to a cat unit. The activity of this specimen of hispidus corresponds to about 12 per cent. of Merck's amorphous strophanthin—an activity that has been hitherto unsuspected, we believe.

Conclusions.—The cat affords a simple method of standardizing the drugs of the digitalis group. The method is available for the retail pharmacist who will devote as much care to the process as is required in the chemical assay of opium.

The cat affords a means of comparing the activity of the several digitalis bodies on the human heart. This is not possible on the frog by present methods.

With some of the digitalis bodies, notably digitoxin, the minimal lethal

---

*Since this paper was read at Richmond we have tested a tincture of strophanthus made by the pharmacopoeial process and found that it did not represent the seed fully, but the marc yielded no active principle to boiling water. Another tincture prepared from the same specimen of seed after removing the fixed oil did represent the seed fully, 1 Cc. being equal to more than 60 cat units. This suggests that the active principle may undergo some change even during percolation or infusion.

It will be remembered that there is no difficulty in exhausting digitalis either by percolation or infusing the powdered leaf.
dose for the cat by the vein is determined more conveniently by injecting about one-half of the lethal dose into the vein, and after an interval of about twenty minutes, injecting crystalline ouabain (so-called crystalline strophanthin) until the animal dies.

Crystalline ouabain is capable of replacing any of the digitalis bodies which we have tested so far as the direct action on the heart is concerned, that is, one-half of the fatal dose of any of these digitalis bodies and one-half of the fatal dose of crystalline ouabain will cause death in a short time if they be injected into the femoral vein in the manner described.

The absorption of digitalis and of strophanthus from the alimentary canal is extremely variable; that of strophanthus is far more variable than that of digitalis; for this reason the activity of these drugs cannot be fixed by means of the oral administration.

Cumulation occurs with digitalis to such a degree that no conclusions can be drawn regarding activity from the effects on animals which have been used previously for digitalis, unless many weeks have elapsed since the previous use.

**Cornell University Medical College.**

**The Chairman:** Now, gentlemen, we have before us a report of the Committee of the Scientific Section of the Philadelphia Branch of the American Pharmaceutical Association. This committee on physiologic assay, has compiled a comprehensive report and it is before you. I will ask Dr. Wood to present it to you.

**Dr. Wood:** Gentlemen, I wish to say preliminary to this report, that this committee was appointed this spring, and we have not had as much time as we would have liked, to investigate some of the points which come up in this connection. This report represents the work of Dr. Githens, Dr. Hofer, Dr. Scott and myself.

Dr. Wood then read the report as follows:

**REPORT OF COMMITTEE ON PHYSIOLOGICAL ASSAY.**

The Committee on Physiological Assay of the Philadelphia branch of the A. Ph. A. has considered the advisability of introducing into the Pharmacopoeia physiological tests for the following drugs:—apocynum, convallaria, digitalis, squill, strophanthus, aconite, gelsemium, lobelia, veratrum, cannabis, ergot, pepsin, suprarenals, thyroid, chenopodium, granatum, kousoo, santonica, cimicifuga, gossypii cortex and phytolacca.

Cimicifuga, gossypii cortex and phytolacca seem of too little importance to acquire physiological standardization.

The vermifuges, chenopodium, granatum, kousoo and santonica, might, we believe, readily be standardized according to the method which was employed by Brunning (Zeit. Exper. Pharm. u. Therap., 1905-I-80) in connection with the oil of chenopodium. He determined the vermicidal effect upon the intestinal worms obtained from the alimentary tracts of dogs and cats. Inasmuch, however, as we are unaware of any application of this method for the process of standardization and as time was insufficient for experimental work on the part of the Committee, we do not feel inclined to recommend the introduction of physiological tests in connection with these drugs, although we would call the attention of the Committee on Revision of the Pharmacopoeia to the possibility of such standardization.
Cannabis.—Two standards have been suggested for cannabis indica. That which is most frequently employed is the amount which is required to produce muscular incoordination in the dog. The other is the amount required to produce narcosis in the frog. As regards the second of these tests, the fact that cannabis indica is practically insoluble in water and that frogs are very susceptible to the action of alcohol seems to us to preclude its use. In regard to the first test, it has been the universal experience that there is a large variation in individual susceptibility in different dogs, so that to obtain results which are even approximately accurate, it is necessary to use the same dog repeatedly. The prolonged use of the drug, however, appears to beget a certain amount of immunity toward it so that one dog can be used for only a comparatively small number of tests. Even with the utmost precautions, the results are far from accurate. As it is impossible on account of individual idiosyncrasies and the uncertainty of the end reaction, to definitely assign any dose and as the results are so inaccurate, we feel that until some more satisfactory means of standardizing cannabis indica has been suggested, no physiological assay process should be introduced into the Pharmacopoeia.

Ergot.—Another drug which urgently requires some method of standardization is ergot. The cock's comb test, as has been shown by Edmunds and in our own experiments, is unreliable. Two other methods have been suggested for this purpose, one based upon the activity of the drug upon uterine muscle and the other based upon its effects upon the circulation. Each of these methods requires either that the sample be compared to a standard preparation or else that a considerable series of animals be employed for each test and the average taken of the series. Against the method of comparing the effects with a standard preparation, rises the almost insuperable obstacle of keeping a standard preparation on hand without deterioration. Our opposition, expressed in connection with digitalis, to any method of test for any drug which requires comparison with a standard preparation unless the standard preparation can be made by any competent pharmaceutical chemist, applies still more strongly to ergot. The method of taking the average of a series makes the assay so expensive and so tedious as to practically preclude its use by any but the largest wholesale manufacturers. Moreover, there is at least a reason to hope that before the next edition of the Pharmacopoeia appears, a satisfactory chemical test for this drug will have been devised. For these reasons we do not recommend the introduction of a physiological standard for ergot.

Thyroid.—Thyroid gland does not in our opinion require physiological standardization as the work of Hunt has shown that the percentage of combined iodine is an accurate indicator of the quality of the drug and we believe that where a chemical test is equally available it should be given the preference to a physiological one.

Veratrum.—The one physiological test for veratrum which as far as our reading goes, has been suggested, is the quantity required to kill. As this substance contains a number of alkaloids which are quite different in their effect, we do not believe that such a test is of any great practical importance. Moreover, as the active principle of this drug is alkaloidal in nature, it would appear to us that a method of chemical standardization could be devised. We would call attention to the fact, however, that the total percentage of alkaloid is no indication of physiological power of the drug, for as has been shown by Eden (Archiv. f. Exper. Path. u. Pharm. xxix, page 40) the protoveratrine which constitutes a comparatively small percentage of the alkaloidal content of the plant is so much more powerful than any other principle that it practically dominates the action of the drug.

Aconite.—Although the Pharmacopoeia directs that aconite should contain 0.5 of 1 per cent of aconitine, yet the method described gives rather the total alkaloid of the drug. The percentage of total alkaloid is by no means an accurate criterion of the activity of the specimen since there are present in the crude drug at least two other alkaloids besides aconitine, which are greatly inferior in potency; therefore the drug might
assay comparatively high in alkaloid but be of feeble physiological power. We would recommend, therefore, the introduction of a physiological standard for this remedy. E. R. Squibb suggested a method of physiological standardization based on the power of aconite to cause tingling of the lips. A definite amount of the drug is rubbed up with 1 cc. of water and held in the mouth for one minute. This should cause a tingling of the lips, coming on in about twenty minutes and lasting an hour. This test is unreliable both because of the difference in susceptibility of different persons and because of the great variations in the susceptibility of the same individual on different days. The standard which we would suggest is based upon the amount required to kill a given weight of animal within a period of twenty-four hours. The fact that guinea pigs may be readily obtained and are so easily handled makes them the most available animals for this purpose.

*Aconite* shall be of such strength that it requires not less than 0.4 Mg. nor more than 0.5 Mg. per Gm. body weight to kill a guinea pig when tested in the following manner:

From the specimen to be tested a fluid extract is made according to the official process. Four guinea pigs are then carefully weighed and into two of them is injected beneath the skin of the belly an equivalent of 0.0004 Gm. of aconite for each gram of body weight and into the other two is injected 0.0005 Gm. per gram body weight. If at the end of twelve hours the first pair survive and the second pair are dead, the drug is of satisfactory quality. If the first pair die it is too strong; if the second pair survive it is too weak. If one of either pair lives and the other dies the test should be repeated.

*Digitalis Group.*—Apocynum, convallaria, digitalis, scilla and strophanthus are placed together by physiologists, as they have much the same physiologic action. As there is no satisfactory method of chemical standardization for any of these drugs, the Committee feels that the adoption of physiologic method of assay would be advisable.

Three types of test have been suggested for the standardization of these drugs (1) the dose required to kill a warm-blooded animal, as the guinea pig; (2) the amount required to produce arrest of the heart in a frog in a given period of time; (3) the degree of elevation of blood pressure in a warm-blooded animal. The last of these methods may be immediately excluded as being the least reliable of the three and also the most complex technically. Concerning the choice between the first two methods, while recognizing that there are valid arguments in favor of each, we are inclined to prefer the test upon the guinea pig. It is true that in the study of Edmunds and Hale (Hygienic Laboratory, Bull. No. 48) the frog test appeared to be somewhat more accurate, showing in no case an error of more than 10 per cent. There are, however, two serious objections to the frog method as an official process of assay. In all of these frog tests a time limit has to be given and the various time limits have ranged from one to twenty-four hours. According to the authors just quoted, the fatal dose for twelve hours is about $\frac{3}{4}$ of that for one hour. It is evident that the difference between the dose required to kill in one hour and that required to kill in twelve hours is largely a question of the rapidity of absorption. Now it may easily be that a preparation which is highly active may, for some reason, be comparatively slowly absorbed so that the one-hour test is a test not only of activity of the drug but of absorbability, which manifestly is not the purpose of the assay.

Another objection which seems to us almost insurmountable is the great variation in the susceptibility of frogs. In the first place, it is a well recognized fact that frogs of different species vary widely in their susceptibility to members of the digitalis group. It would therefore be essential to use always frogs of one species. This offers no trouble if the tests were to be carried out only in one part of the United States, but the species of frogs which are common in Maine and are not found at all in California. The most widely distributed frog, the Rana pipiens, does not occur west of the Sierra Nevada.
Not only do frogs of different species show variations in their susceptibility, but it is recognized that the season of the year influences this. According to a statement made by Dr. Hale in a discussion of this subject before the Philadelphia branch of the A. Ph. A. this difference is due simply to the effects of temperature and can be overcome by working always in a room of certain temperature. We are not familiar, however, with any experimental proof of this statement, and it seems, a priori, improbable. Moreover, there is reason to believe that even the same species of frog varies not only according to the time of the year but also with the locality from which it is obtained. Dr. Donaldson of the Wistar Institute of Anatomy has found a marked difference in the relation of total body weight to the weight of the central nervous system in frogs of the same species, obtained from different parts of the country. While this does not of course absolutely prove that there would be a difference in the susceptibility to digitalis it necessitates at least a careful study of the comparative susceptibility of frogs of the same species from different regions, before it can be taken for granted that they will be the same.

The only method of overcoming these obstacles would seem to be by comparing the preparation tested with that of a standard preparation. We are convinced that such a method of standardization is undesirable for pharmacopoeial purposes. It would necessitate a distribution either by the Government or the Pharmacopoeial Convention of a standard preparation and although the experiments of Houghton (Proc. A. Ph. A., 1909) indicate that tincture of strophanthus might be available for this purpose, such a standard would have to be tested almost continuously by the distributors and given out at comparatively short intervals. Chance deterioration in the standard might easily result in flooding the market with inferior preparations before the fact was discovered and rectified.

Guinea pigs, on the other hand, are obtainable in all parts of the world. They are already used for standardization of various remedies and their susceptibility to digitalis, as far as known, does not vary under ordinary conditions. Temperature, food, season, weight, and sex do not influence their reaction. We therefore recommend the use of guinea pigs for the determination of the physiological activity of drugs of this group. As the methods of assay for all the members of this group would be the same, we shall describe the test as applied to digitalis only.

Digitalis should be of such strength that when tested in the following manner it shall require not less than 0.35 Mg. nor more than 0.4 Mg. per Gm. of body weight to kill a guinea pig in twelve hours.

Method of Assay.—From the sample to be tested a tincture shall be made according to the official process; four guinea pigs are then carefully weighed and into two of them an amount of the tincture corresponding to 0.35 Mg. of digitalis per Gm. of body weight is injected beneath the skin of the abdomen and into the other two a quantity equivalent to 0.40 Mg. is injected. If both of the first pair survive and both of the last pair die the drug is of satisfactory quality. If, however, both of the first pair die, the sample is too strong or if both of the second pair survive, too weak. If of either pair one survives and one dies, the test should be repeated.

Suprarenal.—If the suprarenal glands remain official in the next revision of the Pharmacopoeia, we believe that there should be some standard of strength introduced. As at present there is no chemical assay available and as the physiological test is one of the simplest of all pharmacological experiments, we recommend the introduction of the following method for the physiological assay of suprarenal glands.

Suprarenal gland should be of such strength that 1 Gm. injected intravenously into a dog shall produce a rise of a mean blood pressure within ten millimeters of mercury of that produced in the same animal by a dose of 0.001 Gm. of the pure active principle when tested in the following manner:
Method of Assay.—A dog weighing between five and fifteen kilograms is anaesthetized by injecting hypodermically 0.008 Gm. of morphine sulphate for each kilo of body weight, supplemented with the use of such quantity of ether as shall be necessary to prevent pain. One of the larger arteries, as the femoral or carotid is then connected with a mercury manometer and the animal allowed to come from under the influence of the ether. No experiments should be begun until at least ten minutes has intervened after the withdrawal of the ether. At the end of this period, the normal pressure should be recorded for a period of at least three minutes and then a dose of 0.001 Mg. of pure active principle for each Kg. of body weight is injected intravenously and the blood pressure observed for at least three minutes. At a period of not less than ten minutes after this injection, a dose of 1.0 Mg. of the sample to be tested is injected in the same manner and the pressure observed again for ten minutes. Ten minutes after the injection of this sample a second dose of the pure active principle of the same amount as the first injection is to be injected. The elevation of the blood pressure at the highest point reached after each injection above the pressure at the time the injection was made is then measured. The rise of blood pressure which was produced by the second injection should be within ten millimeters of the average of the first and third injection.

The Chairman: We have with us to-day, one of the pioneers in the physiological testing of drugs. He was to present us a paper, but was unable to do so in time—Dr. E. M. Houghton, of Detroit. I will ask him to open the general discussion.

Dr. Houghton: Mr. Chairman and Gentlemen: I have listened to the papers read this afternoon on the subject of physiological assay with a great deal of interest. The Section should be congratulated upon the excellent papers read. While listening to them I recalled vividly to mind the situation exactly ten years ago, when I read a paper before the same Section on this subject. From the comments of the listeners of the previous paper, the writer was inclined to feel that he had entered the wrong pew, and that possibly physiological assay would never become a topic of much interest to the members of the American Pharmaceutical Association; but time certainly changes ideas as well as heals wounds, for to-day the subject is of enough interest to fill this room with expectant and interested listeners, and in fact we find the subject of physiological assay is being taken up in the foremost countries of the world and, instead of being condemned, is lauded as quite the proper method for satisfactorily determining the value of important drugs.

A number of questions have been brought up in the papers upon which I desire to offer a few comments, as follows:

Shall we use warm or cold blooded animals for test purposes? Some 14 or 15 years ago, when considering the feasibility of devising methods for the physiological assay of drugs, this question came up very forcibly, but, after two or three years of continuous experimentation on the subject, using a variety of animals, dogs, rats, mice, guinea-pigs, and frogs, I concluded that the latter animals were far and away the most desirable for the purpose intended, chiefly because they could be obtained at almost any time of the year in large quantities and in uniform size and species, also because in the case of the heart tonics the action of the drugs upon the heart muscle could be better studied, since paralysis of the respiratory centre does not produce death in these animals which have the faculty of breathing through the moistened skin when the lung ceases to act.

One of the gentlemen spoke of the use of cats. Personally I cannot believe these animals would ever become popular for this purpose. I well remember an incident that happened while I was doing post-graduate work at the University of Michigan, where we were employing cats for our experiments. We had a young cartman subsidized to bring us cats, but we could not get them at any reasonable price. Work became urgent
about the time of the Christmas Holidays, when one could get away from the classroom to better advantage, and I said to him: "John, can’t you get us some cats somewhere? He replied: "How many?" And I said: "Bring on as many as you can get hold of." Much to my surprise just after finishing my Christmas dinner, who should come up the steps but John, and informed me that he had a whole sleigh-load of cats— I believe there were about 35 of them. What to do with them was a serious question for the moment but not so serious as the disposition of anxious inquirers for lost pets. It had been with much misgiving, since this experience, that I have thought of using felines for laboratory experiments. It seems that John and a partner the night before had made a raid in the town, and we were to hear of it later. Any way so far as I am concerned I shall always feel like avoiding the use of these animals wherever possible, and I am sure that our vivisection friends would criticize us much more severely for using cats than where such animals as guinea-pigs or frogs were employed. For these reasons and others not mentioned it was found desirable to use frogs in place of warm-blooded animals. Since 1854 we have used them in great numbers in our work, and I have not seen any real need for changing the test animal.

There may be considerable variation in the frogs obtained from different sources at different times of the year, but it makes comparatively little difference as to the kind and quality of frogs used provided the variation in resistance is carefully noted by testing the standard under identically the same conditions. You must know the resistance of your frogs toward the standard by which you are to measure the value of the unknown.

For several years we have employed a tincture of strophanthus made according to the U. S. P. 1890, and have found the product to be very stable.

At this meeting I hoped to present a paper upon the particular subject of standards, and to bring to your attention a chemically-pure, crystalline strophanthin obtained from undoubted strophanthus Kombe seeds, but unfortunately the time was too short to fully complete the work, and I can only say that the strophanthin occurs in beautiful white crystals. The seeds contained in the original pods had been identified by Prof. Holmes of London, and were a special importation. I believe the use of this strophanthin as a standard would be of great importance, as it would be a decided step in advance. In the paper which will be published in the near future will be given full details as to method of isolation, identification and such, so that it should not be difficult for a trained chemist or pharmacist anywhere in the world, if they obtain the strophanthus Kombe seeds, to succeed in isolating the material for their standard that would be the same as that proposed.

As to the method of assay as discussed by Dr. Hale, this does not differ materially from methods that I have reported on several times during the past fifteen years. The chief element of difference is the time at which we read the end results, Dr. Hale preferring to examine the heart of the frog one hour after the administration of the poison. In England it has been decided to adopt three hours, while in my work I have used death as the final criterion for reading end results. I have some work under way at the present time to show exactly what influence the element of time may have in this matter, but am convinced that for practical purposes it is best to wait until sufficient time has elapsed for the animals to all succumb, rather than to make a determination from the readings made at any time before. However, there may not be a great difference in the final results obtained.

There are a great many questions in connection with the physiological assay of drugs that I should like to consider, but I do not wish to burden you with too much discussion. One point especially that I believe the forthcoming Pharmacopoeia Revision Committee should keep carefully in mind is the importance of checking up any improvements in methods by proper attention to the physiological properties of the resulting products. To illustrate: in the 1900 Pharmacopoeia it was decided to change the menstruum for
We years, thing an extremely direction. I call sense this I treatment adopt application plication. I given Congress marks, give some physiological marks, as I not physiological Journal contain. Inferior physiological is, Sollman: A. l\ Journal. A. is. As Dr. Matcher Sollman: Chair. Chairman and Lest L. is. Dr. Matcher}

**PHYSIOLOGICAL TESTING OF DRUGS.**

**We** fluidextract of squill. The resulting product, as shown by a paper published in the Journal of the A. M. A. several years ago, when using the new menstruum, was very much inferior to that obtained by the old menstruum, at the same time presenting very great difficulties from a manufacturing pharmaceutical point of view. To a lesser extent the same evil occurred when the menstruum for the fluidextract of digitalis was changed to contain a smaller percentage of alcohol, the resulting fluidextract being very much inferior to that prepared where a menstruum approaching that used for the tincture of digitalis is employed. I hope these and other errors that crept in through the lack of application of physiological methods may be eliminated in the next edition of the Pharmacopoeia.

As to standards, it seems to me that it would be wise for us to get together and in some way spell out what would be the best and simplest method, the method that would give the best results to the medical and pharmaceutical professions. As Dr. Wood remarks, there are four standards under discussion, or rather four methods, and it certainly would not be desirable to us to have four different standards. We ought I believe to adopt some unit for measuring the value based on chemically-pure strophanthin. A physiological unit such as I proposed last year in a paper read before the International Congress of Applied Chemistry in London, and published in the Lancet; I have called this a heart-tonic unit. The original unit was modified somewhat in a paper read before this Society last year, the unit as finally presented being: ten times the normal minimum fatal dose per gram body weight of standard test frogs kept under proper test conditions. This change seemed to be desirable, in order that the number of heart-tonic units in a given preparation of strophanthus or other preparation might not be too large and in a sense comparable to the number of units of antitoxin that are now administered in the treatment of diphtheria and other diseases. On the other hand, it seemed wise to have the unit sufficiently small in value, so that fractions would not have to be considered when one desired to use the drug in doses of a given number of units.

Dr. Hatcher called attention to the great variation in our notion of doses. Certainly the variations are appalling, and some of you may remember that in the paper I presented before the Section last year I called attention to the strength of the various preparations of the heart tonics, in heart-tonic units, when translated over into the doses given in the U. S. Pharmacopoeia. I have in a work which will come out soon, attempted to call attention to some of these discrepancies, to see if we might simplify matters in that direction. Whether we shall be able to do so or not, I am not quite able to say. Lest I take too long, I think this is a good halting point, and I wish to say that it has been extremely gratifying that this question has broadened-out as it has, and I hope it will be possible for us to ultimately agree and adopt a standard not alone for this country but an international standard which will be recognized by all the civilized countries of the world as being the most desirable method of measuring the value of this important class of pharmaceutical products.

**The Chairman:** We have with us this afternoon another pioneer—all these old men are pioneers in the science,—and I trust Dr. Sollman, of Cleveland, will tell us something of his experience.

**Dr. Sollman:** I have done very little in the way of standards, for a great many years, and I do not believe that I could offer anything in that connection, but I have pretty settled convictions on the general subject. It should be superfluous, but unfortunately it is not so, to affirm that standards are an absolute necessity for medical practice. If the physician does not receive them, the striking results which often follow are remarkable, sometimes, but they can not be utilized on that particular point any more. I have heard no one seriously question that when the chemical assay can be applied, it
should be applied. It is most convenient as a rule; it can be carried out in more places than the physiological assay. There are other advantages: it does not require the use of animals; animals are not easily obtained, and there is a serious objection in keeping them; so wherever the chemical assay can be used, no one would use a physiological assay. Now whether the physiological assay can be used within the scope of usefulness, is a thing that has to be determined by investigation; it has to be tried out whether the chemical or the physiological assay gives you the better results. I am convinced that for practical purposes either of those methods would give results of sufficient accuracy. For special scientific purposes, one or the other method might be better. I believe that the greatest accuracy could be obtained by the method which Dr. Hatcher detailed, and it has a further advantage from the scientific point of view, the very ingenious method of furnishing the end reaction with an especially delicate indicator, he can eliminate the difference of time reaction, and in that way can obtain an insight into the therapeutic difference. The theory on which it is based is very plausible, and it shows the special directions in which special methods may be needed. It may be, also, that that is the most feasible method. That is a thing that has to be worked out. I believe if the advocates of the different methods could be gotten together, and contrast their results in a broad-minded way—use each other's methods and become acquainted with them—it would not be at all difficult in that way to get a method which would be generally acceptable, and at the same time thoroughly practicable. I should very much like to see, Mr. Chairman, this Section pass a resolution requesting the American Pharmaceutical Association to recommend physiological standards of drugs to the U. S. P. Convention, for their serious consideration.

Motion seconded.

The Chairman: If it is agreeable, I should like to ask Mr. Lyons to speak to that motion, and give us his views on the same question.

Mr. Lyons: I believe now that the function of the physiological assay is a temporary one. I believe we are under way to chemical processes which will be all-sufficient, but we have not yet arrived there. We must supplement our chemical knowledge, which is yet imperfect, by the physiological tests. The motion which has been made is just the motion I should have wished to offer here. Ten years ago the Committee on Revision of the U. S. P. were forbidden to consider physiological assays; they were not to be trusted; we were given the opportunity to make any number of experiments with chemical tests, and those of you who were present here this morning know that we found no end of trouble in arranging the tests, and in getting them anywhere near approximately accurate. Whether we should have adopted any single one of those tests is a question, but I hope we shall now introduce the Convention to give the subject to a new committee. Whether any one individual method that has been proposed should be adopted, is a question. I wanted to offer one suggestion in connection with the question of unit. I should favor a heart-tonic unit, but it should not be a unit with a definite action that a tincture would produce on any animal, but I should have a heart-tonic unit that would be the effect produced by one milligram, or one-tenth of a milligram, or one-thousandth of a milligram: then you could test it on frogs, or on cats, or on anything.

Mr. Hallberg: Now after the pioneers have been heard perhaps the neophytes can get a word in. Mr. Chairman, I was in the category that was mentioned awhile ago, ten years since, and desiring to be progressive and up-to-date, the Chicago Branch arranged for some physiological assays and a demonstration, recently, and we admired the skill of the operator and the uniformity of the substance. We were very favorably impressed with the practicability of the scheme, but when we got to thinking over it, we
began to figure up something like this: the infusion of digitalis was used upon the frog, and figuring the average weight of a man as being something like myself, it would take 60 Grn. of digitalis—which is rather appalling. Then at the following meeting of the Branch we called in a number of physicians, and we had some more light thrown upon the subject, which impressed us very highly, and had a direct bearing upon this question here, that the constitution—particularly the nervous constitution and organization of the batrachia are not at all similar to those of the warm-blooded animals, and respond entirely different, and with very much indifference, to the effect of the cardiac principles; and, therefore, insomuch as this was fairly demonstrated by the enormous amount that would be theoretically required, we concluded the frog was not the proper subject. I believe that experience has demonstrated that the guinea pig is more closely related to our make-up and organism, than any other animal—far more so than the cat. I believe if any animal is to be used, that the guinea pig, by every consideration, ought to be preferred. Now I am not sufficiently advanced as yet in the subject, to talk about the possibility of these units. I only desire to call your attention to a fact that we pharmacists have known for the last thirty years, that the cost of the difference in the strength and value of clinical preparations of digitalis, rests entirely in the character of the menstruum. If you take the same digitalis leaf and make a fluidextract, requiring I think 75 per cent. alcohol, you will have a preparation comparatively inert, as compared with a tincture made with 50 per cent. alcohol. The principles are not present in the drug, but have to be formed through the action of water, and unless there is sufficient water present in the menstruum you will not have the proper principles formed. Now you know the distinction between the infusion and the tincture.

THE CHAIRMAN: Will you kindly speak to the motion?

MR. HALLBERG: I am speaking to the paper. We pharmacists have got something to say about that—the tincture of digitalis has been shown, I believe, by all the speakers here, and emphasized by Dr. Hatcher, to be the most ideal preparation of digitalis, and it is for that reason that it is made with diluted alcohol, and there is sufficient water in it to form these principles. I am now ready to be convinced as to the practicability of introducing physiological assays into the Pharmacopoeia. I am not opposed to it.

THE CHAIRMAN: The resolution is before you. Are there any objections to it?

MR. FRANCIS: With the Doctor's permission I would like to offer an amendment to his resolution.

THE CHAIRMAN: Will the Secretary please read the resolution?

THE SECRETARY: I believe the motion was that the Scientific Section favors the American Pharmaceutical Association recommending physiological standards to the serious consideration of the Pharmacopœial Convention.

MR. FRANCIS: I would amend that by adding to it the further recommendation that the President of the Association be requested to appoint a committee for the purpose of considering the standards, and determining the best of these, and their final adoption, for use; this committee to report to this Association, perhaps during the present session, or at the next annual meeting. It seems to me that the desirability of having such a committee appointed heartily commends itself, and scarcely requires argument.

MR. HALLBERG: I second that motion.

MR. REMINGTON: The Committee of Revision were met with a similar problem in the question of diphtheria antitoxin; the Committee of Revision accepted the situation, al-
though diphtheria antitoxin, and in fact all serums, were "turned down," if I may use the term, in the Convention; still it was absolutely necessary for the subject to be gone over by the Committee of Revision, and certainly nobody can be found to-day who will object to the conclusions obtained. Now the Committee on Revision met the question of forming a commission of bacterial experts, who considered that question, and the very same idea which I was glad to hear Dr. Sollman advocate, was carried out. That the present Convention will take favorable action upon these resolutions I feel very certain, because if it were necessary to take action during the progress of the revision, certainly it is most necessary to take it now. I don't altogether like Mr. Francis' amendment, because if the committee is to report to the American Pharmaceutical Association, it would leave the matter open for a whole year, and I certainly, for one, feel that this whole subject of physiological assay ought to be taken up at once, as soon as the Committee on Revision is formed; that is one of the very first steps that ought to be taken, so as to give as much time as possible, because some of the formulæ in the Pharmacopæia may depend on the results obtained by this Committee on Revision. I don't think there would be any objection to the appointment of a committee of experts. What has impressed me most to-day is the difference of opinion between these gentlemen who have worked so hard, and to such a valuable extent; but the thing to do is to get together and work together and give a standard for the Pharmacopæia to use.

Mr. Francis: If my amendment is liable to be misconstrued—as it has been by Mr. Remington—I will withdraw it and ask to be permitted to offer it as an independent resolution at a later period. My sole idea was to have this Association appoint a committee to study this important subject, for the next ten or twenty years, and get the best results which have been obtained by the people who have been studying the subject.

The Chairman: If Mr. Francis withdraws his amendment, then the motion as originally presented by Dr. Sollman, is that the Scientific Section favors the American Pharmaceutical Association recommending the physiological standard of drugs to the serious consideration of the U. S. P. Convention.

Carried.

Mr. Francis: I would offer a resolution as follows: In view of the great attention being paid to the subject of physiological assay by many workers in this country and Europe, and as quite a number of physiological methods have been discussed, for the standard of some of the important drugs, I would suggest that a committee of not less than five members be appointed by the President of the American Pharmaceutical Association to consider such methods, and report at the next meeting, said committee to be known as the Committee on Physiological Assays.

The Chairman: That is a resolution that will have to go up to the general session of the Association. Are there any further remarks?

Mr. Vanderkleed: In regard to these apparent differences, I would assure those who have done no work in physiological assay, that the differences to-day are less than in many of the chemical assays now in the Pharmacopæia, and just as concordant results will be obtained by any of these methods, and by the different workers, as was the case by some of our chemical methods.

Mr. Lyons: If we have a committee appointed, I would suggest that a man be selected who shall be able to organize the work Dr. Francis talks of here; a single man would be better than five, and he would be responsible.

Mr. Turner: Why would it not be more expedient for us to have the Chairman of
the Scientific Section appoint the Committee, and let the report be made to this Section next year. Is there any objection to that?

Mr. Francis: I would naturally assume that the committee would report to the Scientific Section.

The Chairman: It would not—unless it was a committee of the Scientific Section; it would report to the Association direct.

Mr. Francis: The appointment of the members of this committee is a mere matter of detail. What I have in mind is that we have pharmacologists in the manufacturing establishments, gentlemen in the public service, and also gentlemen who are connected with the teaching staffs of various schools, working on this subject, and they are practically the ones who are doing all of this work that is being done to-day. My idea is to have a committee of such dignity that the results they obtain will have the proper consideration, but whether that committee should be appointed by the Chairman of this Section, or by the Society at large, is a matter of no importance to me.

The Chairman: I am not sure, but I should imagine that the work of a committee of this kind would entail the expenditure of some money, and so far as this Section is concerned it has no available funds; therefore, it would perhaps be better to follow Dr. Francis' original idea and have a committee of the Association.

The motion of Mr. Francis was here voted upon and carried.

The Chairman: Mr. Sayre is on the program for to-morrow, on a closely related subject, "Gelsemine and Other Constituents of Gelsemine Root, and Remarks on Assay of Preparations"; and if there is no objection I would like to have him briefly present this matter to you at the present time.

Mr. Sayre: Mr. Chairman, this is rather an unexpected call. I have samples in my room which I expected to present, but I can present those at some other time. I will simply present the paper by title at this time, and if the Chairman will allow me I will be very glad to show these various samples to the members at some other meeting.

"GELSEMININE AND OTHER CONSTITUENTS OF GELSEMIUM."

L. E. SAYRE.

The work of the past year upon gelsemium has been directed mainly to the study of the alkaloid gelseminine. The crude material which was reported on last year was obtained from 50 pounds of ge'semium root. See Proceedings, 1909. This crude product was in the form of a soft extractive, having highly alkaloidal properties.

What has been recognized hitherto as gelseminine is a soft resinous alkaloidal residue remaining after gelsemine hydrochloride has been crystallized from alcoholic solution of the mixed alkaloids. Thompson* first announced this as a second alkaloid. Cushny regarded it as a powerful poison resembling coniine. Whether this is a distinct alkaloid, a polymerized form of gelsemine, a mixture of various uncrystalline principles of unknown composition, has not been determined. Our work this year has indicated that it is a complex substance. We have been able to separate

* Pharmaceutical Era, 1887, p. 3.
it into at least two distinct bodies, having different solubilities and different reactions with agents.

The crude gelsemine for our work was obtained by the Thompson method and by two different modifications of it, as follows:

**METHOD A.**

A one-fourth portion of the soft alcoholic extract obtained from 50 pounds of drug (see Proceedings, 1909, p. 902) was treated with a 2 per cent. solution of $H_2SO_4$, the acid solution thoroughly washed with chloroform by which all the gelsemic acid seemed to be removed. The acid solution was made alkaline and shaken with ether-chloroform (5:1) until exhausted and the separated ether layer washed with 2 per cent. HCl. On concentrating this liquid in vacuo, the residue consisted mostly of soft resinous-like reddish gelsemine hydrochloride, seemingly very little or no white alkaloid, gelsemine, being present.

**METHOD B.**

In this case the soft extract ($\frac{3}{4}$ portion) was first treated with an equal bulk of lime and dried, after which it was treated with 2 per cent. $H_2SO_4$. The acid solution was washed with chloroform and the subsequent treatment was precisely similar as in Method A, using the solvents in the same order. The final acid aqueous washing of the chloroform-ether solution of the alkaloids was concentrated in vacuo to small volume. The evaporation was continued to dryness and the dry product powdered. The powder, which was quite dark, was treated with alcohol. This left 2.1 Gm. of the colorless salt, gelsemine hydrochloride.

The separated alcohol solution was concentrated and set aside to crystallize, but no more crystals appeared. The concentrate corresponded to Thompson's gelsemine. It was a red, soft, gummy, resinous mass, with strong alkaloidal reaction, and had a very bitter taste.

**METHOD C.**

A third portion, consisting of the remaining half of the original extract, after making alkaline, was extracted with benzol. The solution was filtered and shaken out with 2 per cent. $H_2SO_4$; the acid solution was then washed with chloroform to remove gelsemic acid. The subsequent treatment with the immiscible solvents was the same as in Method A, the liquids being used in the same order. The acid solution was then concentrated in vacuo to small volume and set aside to crystallize. Colorless crystals of gelsemine hydrochloride separated, which, after washing with U. S. P. alcohol and drying in vacuum desiccator, weighed 11.5 Gm. This method gave the largest yield of gelsemine hydrochloride. The liquid from which the crystals were removed gave, on concentration, a residue characteristic of Thompson's gelsemine hydrochloride.
All of these products (crude gelseminine) from Methods A, B and C were separately subjected to further examination in the hope of obtaining more definite information concerning this soft, resin-like alkaloid.

It may be well to state in passing that crude gelseminine gives with manganic oxide and H₂SO₄ a purple color, while gelsemine gives a cherry-red. The final color of gelsemine merges into green, fading to a yellow.

The suspicion has been entertained that the so-called gelseminine consists of possibly a mixture of coloring matter and another alkaloid persistently combined therewith. The persistent "combination" referred to has not thus far been possible to break up by any ordinary means of alkaloidal separation. Thompson's gelseminine is, by another theory, a derivative of the colorless alkaloid or of esculin, having somewhat the same relation to gelsemine, as does chinodine to quinine. Indications seem to be that gelseminine, when obtained pure, will prove itself to be a colored alkaloid, producing colored salts.

It might be well to state here also that the physiological tests of the crude gelseminine hydrochloride, formerly produced by us, indicate that it differs from gelsemine in being about ten times more toxic than gelsemine.* Cushny found that its action was very similar to that of conine, was more depressent to the central nervous system, and had mydriatic properties, but as such, was too irritating for practical use. Some authorities state that the effects of the crude drug are mainly due to the uncrystalline alkaloid gelseminine, and not the crystalline gelsemine. In order to study the constitution of this gelseminine, it is evident that it must be brought to a more definite physical and chemical condition. In attempting to do this, the three crude gelseminines, A, B and C., as above stated, were made the starting point.

Examination of Crude Gelseminine (A).—This consisted of a reddish colored product, which when dried in a current of warm air weighed 19.92 Gm. This product, by solution in acidulated water, precipitation by ammonia, washing out by immiscible solvents, twice repeated, yielded crude crystals of the colorless gelsemine hydrochloride, which when purified weighed 0.6556 Gm. It was thus made clear that a fair proportion of the so-called crude gelseminine (A) consisted of the alkaloid gelsemine.

All attempts to purify or crystallize the remaining soft, resinous, alkaloidal substance from which the gelsemine hydrochloride had been separated was of no avail. It persistently remained as a colored mass which dried, in a thin layer, into a hygroscopic, scaly salt.

Examination of Crude Gelseminine (B).—Treated with absolute alcohol it was found to be not entirely soluble. 6.5 per cent. remained undissolved, but the insoluble portion could not be deprived of its coloring matter. It was probably a mixture of gelsemine and gelseminine.

* Dr. E. D. Reed, Pharmacologist. See Proceedings A. Ph. A., 1908, p. 855.
1.6355 Gm. of crude gelseminine (B) containing 17 per cent. of moisture, corresponding to 1.3574 Gm. of dried material, was precipitated from an acidulated solution by means of ammonia in excess.

The liquid containing the suspended alkaloid was transferred to a filter and continuously washed with ammoniacal water until the washings ceased to show presence of alkaloid.* The residue on the filter was then transferred to ammoniated water and allowed to macerate for several hours. The liquid was transferred to a filter and again washed as before. The insoluble precipitate was carefully dried in a vacuum desiccator. It weighed 0.4752 Gm., thus indicating a distinct separation. One of these separated products (insoluble in ammonia) we designate as gelseminine (B₁), the other (B₂).

The ammoniacal filtrate was separated into three portions; the first portion passing through the precipitate and filter was of a pinkish color; the second portion was less colored, and the third portion colorless. These three solutions were separately dried in a vacuum desiccator, which was supplied with a current of air made dry by a battery of Woulfe bottles containing sulphuric acid, and finally a U-tube of calcium chloride, a partial vacuum being maintained. Practically dry products were thus obtained, (Gelseminine, B₂).

The first residue† was brittle and of a reddish color. The second residue was of a lighter yellow, and the third was practically colorless. All three were alkaloidal—the third, colorless residue, was also alkaloidal and contained insoluble material. The total weight of the alkaloid soluble in ammonia was 1.1584.

(B₁): The precipitate insoluble in ammonia was first dissolved in dilute sulphuric acid, transferred to a separator, made alkaline with ammonia; the alkaline solution washed with chloroform, which readily extracted the colored alkaloid. The chloroform solution was transferred to a second separator, and after washing, the distilled water was washed with dilute hydrochloric acid. This last washing removing practically all of the color and the alkaloid. This was placed in a vacuum desiccator and dried as was the former solution. The weight was 0.4752 Gm.

It should be noted here that the alkaline aqueous red solution (B₂) when washed with chloroform, yielded practically no color or alkaloid, the coloring matter as well as alkaloid remaining in the alkaline fluid. On the other hand, the alkaloid from B₁, with its red color was readily transferred to chloroform when its solution, made alkaline, was shaken out by that solvent.

Examination of crude Gelseminine (C).

---

* We have noted before that some of the alkaloids of gelsemium seemed to be remarkably soluble in ammonia.

† This was necessarily contaminated with a small proportion of NH₄Cl.
Treated with absolute alcohol, this was found to be entirely soluble.

1.435 Gms. of Gelseminine (C) containing 10 per cent. of moisture was taken, precipitated by ammonia, and succeeded by the same treatment as that to which the former product (B) was subjected. The precipitate insoluble in ammoniacal water weighed 0.0835 Gm. (5.81 per cent.), and had the same characteristics as the former insoluble precipitate.

These three, apparently distinct, alkaloids (gelsemine, gelsemoidine (?) and gelseminine) will be studied carefully in the future.

PHYSIOLOGICAL STUDY OF THE THREE ALKALOIDS.

Professor H. W. Emerson makes preliminary reports on the pharmacological examination of these various alkaloidal products upon frogs, as follows:

An aqueous solution of 0.010 Gms. to Cc. was employed.

Weight of frog 39.8 Gms. Normal heart rate 60 a minute.

3:45 p. m. Injected 0.3 Cc. of the solution into the lymph sac of the frog. 3:45 p. m. Heart rate 52. 3:50 p. m. Heart rate 40. 4:00 p. m. Heart rate 35. The heart rate lowered and the amplitude increased. 4:05 p. m. heart rate 32.

4:05 p. m. Injected 0.5 Cc. 4:10 p. m. Heart rate 36.

4:20 p. m. Injected 0.5 Cc. more. 4:30 p. m. Heart rate 30. 4:45 p. m. Heart rate 24. 5:00 p. m. Heart rate 24.

5:05 p. m. Injected 0.5 Cc. more. 5:10 p. m. Heart rate 11 and weak. 5:15 p. m. Heart rate 5 and very weak.

Gelsemine Hydrochloride first slows the heart and causes more complete contraction and expansion. As the dose is increased, the beats are slower and slower, and the heart continually grows weaker.

2. Crude Gelseminine Hydrochloride (soft resinous extractive). This preparation was made in the same manner and of the same dilution as the first.

Weight of frog, 68.5 Gms. Normal heart beat 61.

9:05 a. m. Injected 0.2 Cc. of this solution into the lymph sac of a frog. 9:15 a. m. Heart rate 60. 9:25 a. m. Heart rate 60.

9:35 a. m. Injected 0.3 Cc. solution.

9:42 a. m. Heart rate 36. 9:48 a. m. Heart rate 30. 10:02 a. m. Heart rate 30.

10:03 a. m. 0.5 Cc. solution injected.

10:08 a. m. Heart rate 28. 10:15 a. m. Heart rate 28. 10:52 a. m. Heart rate 24.

10:55 a. m. Injected 0.5 Cc. solution.

11:00 a. m. Heart rate 18. 11:10 a. m. Heart rate 18. 11:25 a. m. Heart rate 18. 11:45 a. m. Heart rate 18. 12:00 a. m. Heart rate 14 and weaker. 12:40 p. m. Heart rate 12 and weaker. 1:00 p. m. Heart
rate, 10. 1:50 p.m. Heart rate 10. 2:10 p.m. Heart rate 8. 2:37 p.m. Heart rate 5. 2:45 p.m. Heart ceased to beat.

3. Gelsemine (B.) (soluble in NH₄OH). The solution of this preparation was made in the same manner and of the same strength as the first. Weight of frog, 52 Gms. Normal heart rate, 60.

9:47 a.m. Injected 0.2 Cc. of solution.
9:52 a.m. Heart rate 51. 10:04 a.m. Heart rate 51.
10:05 a.m. Injection 0.5 Cc. solution.
10:15 a.m. Heart rate 50. 10:39 a.m. Heart rate 60.
10:45 a.m. Injected 0.5 Cc. of the solution.
10:50 a.m. Heart rate 45. 11:05 a.m. Heart rate 50. 11:25 a.m. Heart rate 50.
11:30 a.m. Injected 0.5 Cc. of the solution.
11:45 a.m. Heart rate 24. 12:00 m. Heart rate 24. 12:40 p.m. Heart rate 21.
12:45 p.m. Injected 0.5 Cc.
1:05 p.m. Heart rate 18. 1:35 p.m. Heart rate 18.
1:50 p.m. Injected 0.5 Cc.
2:00 p.m. Heart rate 21. 2:25 p.m. Heart rate 28. 2:40 p.m. Heart rate 29.
2:45 p.m. Injected 0.5 Cc.
3:20 p.m. Heart rate 25. 3:30 p.m. Heart rate 25. 5:00 p.m. Heart still beating. 6:00 p.m. Heart still beating. 8:00 p.m. Heart still beating. This preparation does not exert as marked a slowing of the heart as did gelsemine (colorless) and crude gelsemine (soft extractive.)

4. Gelseminine (B.).—This solution was made in the same way and of the same strength as the preceding solutions. Weight of frog, 33 Gm. Normal heart rate, 65.

10:40 a.m. Injected 0.2 Cc. of this solution.
10:55 a.m. Heart rate 60. 11:10 a.m. Heart rate 54. 11:15 a.m. Heart rate 49. 11:30 a.m. Heart rate 49.
11:45 a.m. Heart rate 30. 12:00 m. Heart rate 28. 12:40 p.m. Heart rate 26. 1:05 p.m. Heart rate 23.
1:10 p.m. Injected 0.5 Cc.
1:40 p.m. Heart rate 10. 1:52 p.m. Heart rate 8. 1:57 p.m. Heart rate 6. 2:20 p.m. Heart rate 5. 2:40 p.m. Heart ceased to beat.

Experiments to determine toxicity of the different preparations:
The preparations were each made 0.010 Gm. of the alkaloidal salt to the Cc.

Preparation No. 1. Gelsemine hydrochloride (colorless).
Preparation No. 2. Gelseminine hydrochloride (soft ext.).
Preparation No. 3. Gelsemoidine (?) (soluble in ammonia, B₂).

Preparation No. 4. Gelseminine hydrochloride (insoluble in ammonia, B₂).

Four frogs of about equal weight—weights from 30 to 35 Gm.—were taken:

**SUMMARY.**

The preliminary physiological results seem to show:

1st. That gelsemine hydrochloride, contrary to statements formerly
made by pharmacologists, has an inherent power as a heart depressant, preceded by a period of excitation.

2d. That the alkaloid soluble in ammonia (B₁), which if found to be a separate alkaloid we may name gelsemoidine, is less powerful than gelsemine as a heart depressant.

3d. The alkaloid gelseminine (insoluble in NH₄OH), B₃, is depressant and less toxic than any other one of the poisonous principles. They all seem to exert, in different degrees, a paralyzing action.

It is understood that this is but a preliminary report. Tracings have been made of this work, and similar tracings will be made, using larger animals. In studying relative toxicity others observations were made which will be reported later.

**ANALYSIS (COMBUSTION) OF GELSEMINE HYDROCHLORIDE.**

The combustions of Gelsemine Hydrochloride were carried out in the usual way, using a silver spiral to take care of the chlorine and a reduced copper spiral to break up nitrogen oxide compounds.

Combustions for carbon and hydrogen.

No. 2. Carbon 66.34 per cent. Hydrogen 6.41 per cent.

Combustions for Nitrogen.

No. 1. Nitrogen = 5.68 per cent.
No. 2. Nitrogen = 5.59 per cent.

Carius Method for determination of chlorine.

No. 1. Chlorine = 13.00 per cent.
No. 2. Chlorine = 13.60 per cent.

Oxygen by Differences.

No. 1. — 7.78.
No. 2. — 8.66.

Formula for Gelsemine Hydrochloride, using the atomic weights of United States Pharmacopoeia. H = 1.

C₁₄H₁₂NOHCl.

Percentage of, obtained by combustion.

The formula then for the alkaloid would be $C_{14}H_{15}$NO.

It will be noted that this is a different molecular formula for this alkaloid than that obtained by Thompson and by Gerrard (Phar. Era, Jan. 1887, p. 3).

**ASSAY OF PREPARATIONS OF GELSEMIUM.**

In the Proceedings of the American Pharmaceutical Association ('08, p. 856), our experience in the assay of preparations of Gelsemium are recorded. We there recommend the Webster process. Since that time we have been obliged to employ less elaborate methods. This has been brought about by our connection with the State Drug Laboratory, for the analyses of drugs under the Pure Food and Drug Law. In this work it is frequently necessary to quickly separate the grossly substandard material from the standard. We have found that this can be done best by a short and rapid process; a process that will give at least approximate results. For this purpose I have much respect for Mayer's Reagent in estimating alkaloids. We quite agree with Dr. Lyons,* that the precipitate produced by this reagent, is of a sufficiently constant composition as to be available for purposes of gravimetric estimations. With few exceptions, when approximate results are contemplated, these precipitates are available. In the case of Gelsemium, when we have a mixture of colorless and colored alkaloids to deal with, and when titration, consequently, is difficult and uncertain, the process of precipitation is especially advantageous. For this purpose, the alkaloidal solution must be brought to a certain dilution, the alcohol driven off of the preparation by a low heat and the solution acidulated. The reagent is then added in excess, the precipitate allowed to stand several hours before collecting, washed carefully (washing filter rather than the precipitate), dried at $100^\circ$ C. and weighed. By this method we have been able to obtain as concordant results as by the more elaborate processes, and I may add, we have been somewhat surprised at the reliability of these results. If the analyst establishes for himself the relation between the weight of the Mayer's reagent precipitate (obtained from solution of uniform dilution), and the weight of the combined alkaloids of gelsemium, which can be done by the more elaborate processes, he can safely employ the Mayer's reagent as above indicated and obtain reliable results concerning the alkaloidal strength of gelsemium preparations. We have proven this satisfactorily to ourselves by repeated experiments with "unknowns" worked out by ourselves and others in the laboratory.

**The Chairman:** The Chairman desires to apologize to the readers of the previous papers for his remissness in not giving them an opportunity to close the discussion, but he took it for granted that the disposition made of the matter was satisfactory. We now have before us two papers on alcohol; one of them being "Determination of Methyl  

---

*Amer. Jour. of Pharmacy, Jan. 1887, p. 5.*
Alcohol in Ethyl Alcohol," by H. Englehardt and H. W. Jones. They not being present we will pass the paper by title. The other paper is on "Commercial Alcohol and the U. S. P. Requirements," by Samuel L. Hilton. This paper contains some important matter which I think we should consider and act upon.

Mr. Hilton here read his paper.

COMMERCIAL VS. U. S. P. ALCOHOL.

BY S. L. HILTON.

For the past year I have collected specimens of as many different brands of alcohol as I have been able to procure on the market in Baltimore and Washington, for the purpose of careful examination, as to conformity to the requirements of the U. S. P. and also, as to whether the requirements of the U. S. P. are too rigid or deficient.

Of the fifteen examinations tabulated below, the first four conform to all of the requirements of the U. S. P. and were purchased from one manufacturer at four different times during the year; samples No. XI and XII also conform to the present standard, the remaining samples, nine, are below the requirements and were rejected. They all show an excessive amount of total solids, decided reactions for tannin and aldehyde, and excessive amounts of organic impurities; all samples were free from methyl alcohol.

For many years and previous to 1906 a large amount of the alcohol of commerce was composed of what is known as heads and tails, that is the first and last parts of the distillate, both of which are heavily contaminated with congeneric products which render alcohol unfit for medicinal purposes. In a product of this kind there are more than forty of these congeneric products, many of which are difficult of detection, and the U. S. Pharmacopoeia should prescribe more definite requirements for the discovery of them than the mere blotting paper test. In the best samples I have examined furfurol is always present in amounts varying from $\frac{1}{3}$ of 1 per cent. to $\frac{1}{3000}$ of 1 per cent., while I have not attempted the isolation of other congeneric products I believe that satisfactory tests can be devised whereby the more important of these products can be detected easily and a maximum standard for them adopted.

The test for weighable residue is indefinite, the U. S. P. directs that 50 Cc. of alcohol be evaporated in a clean glass vessel, no color or weighable residue should remain. What temperature should be used for the evaporation? The temperature should be sufficiently high to drive off all volatile matter and the residue I would suggest be dried at 115° C., the vessel and contents should be cooled in a dessicator for at least half an hour before weighing. With respect to what is a weighable residue, what is meant? A weighable residue determined on an ordinary prescription balance would mean something more than .001, while with an analytical balance .0001 is
easily detected. The German Pharmacopoeia is more definite in this particular and states that the residue should not weigh more than .0005, this standard is specific as all standards should be whenever possible and I would therefor then suggest that the evaporation of 50 Cc. of alcohol for residue be conducted at 115° C., cooled in a dessicator for at least one half hour, and should not weigh more than .0005.

The spontaneous evaporation is not very satisfactory, for the reason, it is slow, the product is likely to become contaminated with foreign matter and the treatment of the residue with sulphuric acid does not differentiate what products remain.

Potassium hydroxide tests show presence of both aldehyde and tannin, some means should be used to distinguish each.

The silver nitrate test is exceedingly sensitive and perfectly satisfactory.

The methyl alcohol test should be more delicate, the present test does not claim to detect less than 2 per cent.

From the examinations I have made I am convinced that Alcohol that has been stored in wooden barrels, no matter how carefully the barrel has been previously prepared, will always show the presence of tannin and if kept for any length of time in the barrel is likely to contain oxidation products. No sample that had been stored and shipped in barrels came up to the requirements of the U. S. Pharmacopoeia. Here I desire to call attention to the fact that the regulations and instructions concerning distilled spirits are exceedingly explicit and require distillers to place distilled spirits in wooden containers known and described in the regulations of the Internal Revenue Bureau, as a distiller's package, while these packages are no doubt satisfactory for spirits used as beverages they are far from being so for high test alcohol; however, under the same regulations provisions may be made whereby metal, glass and earthenware containers can be used, provided they are encased in wood in such a manner that the casing can not be removed from the vessel without destroying the utility of both; however no incased vessels are permitted to be used, by distillers, unless one of said vessels, or a model thereof, has been presented to the Commissioner of Internal Revenue and received his approval. Herein lies the crux of the situation, and if the American Pharmaceutical Association through its officers will take up this matter with the Commissioner of Internal Revenue, present in a proper manner the facts, I am sure a form of package known as a glass carboy or tinned iron can, when properly encased would be permitted to be used as a distiller's package and thereby the retail druggist would be enabled to obtain his alcohol pure and free from contamination, at a fair price, and provided it was properly distilled and purified would conform to all of the requirements of the U. S. Pharmacopoeia.

</table>
Mr. Hilton: I would further like to state that in all the specimens of alcohol I have examined, I am firmly convinced that the alcohol with the exception of heads and tails, as it leaves the still conforms to the present requirement of the U. S. Pharmacopoeia, and the trouble is entirely with the form of package in which it is stored and shipped.

Mr. Hallberg: I would like to ask Mr. Hilton whether he means all the alcohol, or the middle run only?

Mr. Hilton: Well, as I understand it, the first portion of the distillate that comes off from the batch should be rejected, and likewise the latter portion. The middle portion, that is being put out by the manufacturer to-day, will conform to every one of those requirements, even the requirements I have suggested, without any trouble, provided it is not stored in a wooden container. If it is stored and shipped in a glass or tin or iron container, it will conform to those requirements. I have taken up the matter with the officials of the Bureau of Chemistry in Washington, with regard to a galvanized steel container, and they have demonstrated by experiment that there is some action which takes place after the alcohol is stored in a galvanized steel container, which produces quite a number of oxidation products. I intended to bring along with me a sample of so-called commercial alcohol that you could all see. This sample was taken from a barrel that was purchased by the College of Pharmacy in Washington, tax-free, shortly after it was transferred to glass containers and when the alcohol was taken from the barrel it had a decidedly strong odor of ethyl nitrite, showing that there had been some action whereby ethyl nitrite had been generated simply by the product remaining in the wooden barrel.

Mr. Hallberg: Mr. Chairman, the distiller sends three kinds of alcohol out from the run—heads and tails, known as alcohol, and a middle run known as cologne spirits. Now of course to be U. S. P. it should be cologne spirits, or middle run. There are only 20 barrels of middle run, in a run of 100. There are about 30 heads; about 20 to 30 middle runs, and about 40 tails. Now formerly we could go to the distiller and get the middle run—if you knew how—and pay alcohol price, for cologne spirits; but now they sell all of it, heads, tails and middle run, as alcohol, and it is only by accident that you get U. S. P. Alcohol. I believe Mr. Hilton’s contention is correct, provided the alcohol is middle run, but if it is heads or tails he will find it does not conform to the U. S. P. requirements.

Mr. Hilton: I will state in answer to Professor Hallberg’s remarks, that I had one lot of alcohol which was marked “Pure grain distillate,” and the other marked “Cologne Spirits,” and if the two had been submitted to any committee, without their knowing which was which, they would be unanimously of the opinion that the “pure grain distillate” was the cologne spirit—showing that the cologne spirit had been stored in the barrel for months, and in shipping the coating of glue on the inside of the barrel had been broken, which allowed this alcohol to sufficiently leech the wood to produce certain secondary products and so contaminate the alcohol that it was not equal to a presumably lower grade that was sold under the present requirement of pure grain distillate. Now if we can get the Internal Revenue Department to allow the form of package I have suggested as a distiller’s package, it will not cost the retail druggist or the manufacturer one cent. more than it does to-day.

Mr. Cliffe: In connection with this question, we had a sample of alcohol from which we were unable to make spirit of nitre, and we concluded that was due to the presence of tannin from being stored in a barrel.

Mr. Hilton: I will state that alcohol stored for any length of time in a wooden
barrel, will not produce aromatic spirit of ammonia that will conform to the requirements of the U. S. P.

MR. HALLBERG: I make a motion that a committee of one, consisting of Mr. Hilton, be appointed to make arrangements with the United States Internal Revenue Department for a new alcohol container.

THE CHAIRMAN: That does not quite cover the ground that Mr. Hilton was leading to. If you will change your motion to the effect that the Association in general meeting assembled pass a resolution requesting the Commissioner of Internal Revenue to sanction a package, I believe it would give Mr. Hilton something to work on.

MR. HALLBERG: I make such a motion.

THE CHAIRMAN: The motion is made that this Section request the Association in general session to pass a resolution requesting that the Commissioner of Internal Revenue sanction a package which will insure alcohol reaching the retail druggist in fit form for him to use. The question is before you; are there any remarks?

MR. HILTON: There were several samples of alcohol reported on sent to me, presumably U. S. P. alcohol, and I feel confident that the parties who sent it to me, were surprised after they received my report that it was not U. S. P. alcohol; so I take it from that, that evidently the parties sending it expected that it would conform to all the requirements of the Pharmacopoeia.

MR. MURRAY: This discussion has been a surprise to me; there is no difficulty in our getting alcohol in tins.

THE CHAIRMAN: It is not put in tins originally, at the stills.

MR. MURRAY: About three years ago there was a notice in the Journal to the effect that you could buy alcohol warehoused in tins, obtained directly from the stills.

THE CHAIRMAN: If it is taken from the barrel and put in tins holding five or ten gallons, it must bear a United States revenue stamp.

MR. MURRAY: I am advised by the manufacturers that it is originally warehoused in tins, but I may be mistaken.

MR. HILTON: I understood indirectly, but am not in a position to state positively, that the maker of the alcohol of which I report the first four examinations, has been allowed to store his alcohol in copper containers, as a distiller’s package, and in putting the alcohol up for commerce it is then placed in 10 gal. tinned iron cans. I have not only examined four lots of that alcohol, but I have examined about ten lots, and every one of them comes up to the requirements of the Pharmacopoeia, and I can distinctly call to mind two lots that are a great deal better than either one of the four I reported on. Possibly some gentleman located in Boston, or in the New England States, might enlighten us on the subject. The firm from which I procured that alcohol (and I have been using it for two years), is located in Boston. I felt that I could not in justice mention the firm’s name, but I thought possibly some of the members present would recognize whom I referred to, and they might be able to state something in regard to it, without mentioning the name. There is a very serious objection to storing or shipping alcohol in any metal container that is galvanized. The Bureau of Chemistry of the Department of Agriculture stored some of the best grades of distilled alcohol that they could get, in containers of that kind; after the alcohol had been stored in those containers for a few weeks they found there was a decided action on the alcohol, due prob-
ably to some galvanic action between the two metals, so that the alcohol stored was contaminated with quite a number of secondary products, which rendered it unfit, of course, for analytical purposes.

Mr. Patch: It is barely possible that Mr. Hilton expected I would say something about that Boston alcohol. I understand that the Government has purchased from a Boston house a very superior alcohol, that meets all their requirements; it is obtained from the distillation of grain, and I understand it is shipped soon after it is distilled, and it has not had time for any such change. I will say that I have purchased quantities of this alcohol, from the same distiller, and it answers—and more than answers—all that the Pharmacopoeia requires.

Mr. Hilton: I am very glad I have some one to corroborate the statements I made in regard to this particular brand of alcohol.

The Chairman: The question is whether the Department permits at this time the storing and sending out of alcohol in glass containers. If it does, our resolution would be superfluous and unwise.

Mr. Flemer: I obtained alcohol from Boston in the same way, in 10 gallon tin cans, and if that is permissible I do not see why we should recommend any different container, provided the alcohol shipped that way is all right, and I presume it is.

The Chairman: It is not quite; if that alcohol was warehoused in wood, and then put in 10 gallon tin cans, the cans must be stamped, so the presence of a stamp on the can is no indication that it has not been in wood. You would naturally pay a higher price for an alcohol that is transpacked, than you would for an alcohol run directly into a metal or glass container, and if you can get the alcohol run directly into a metal or glass container, for the same price, that you would pay for the other, it is an advantage; but we don't want to pass a resolution here asking for something to be done, which is already being done.

Mr. Flemer: There is no difficulty in obtaining alcohol in box tins, conforming to the U. S. P., and what more we want I do not know.

The Chairman: But we want that alcohol at the same price we are paying for that now in wood containers.

Mr. Flemer: It is the same price.

The Chairman: The motion then, as amended, is that the regulation approved would be that alcohol for medicinal purposes should be stored in tin, iron or glass containers, and not in wood.

Carried.

On motion, the Section here adjourned till to-morrow (Friday) morning, May 6th, 1910, at 10 o'clock.

Adjourned Session—Friday Morning, May 6, 1910.

The Section met pursuant to adjournment, at 10 o'clock, a. m., Chairman Wilbert presiding.

The Chairman: The first paper on the program this morning is by Mr. Dunning.
He has mislaid his paper, and is now searching for it, so if Mr. Murray does not mind we will have his paper first—"The Use of Electricity in Pharmacopœial Testing."

MR. MURRAY: I have a good deal of hesitation in attempting to say anything about electricity. I do not pose as an electrician; in fact I don't know anything about it, but for a number of years I have made a little use of it, just as a man wears clothes, without knowing how to make them. I think the subject of testing by electricity is growing, and becoming important, and possibly a reference to it here at this meeting might do some good. In all my experience with electricity I have been very much pleased with the results, but whenever I have spoken to others about it they have all been sort of mystified, as if something about it could not be understood; and it was for that reason I have brought a few small pieces to show that the work is not so complicated. In this paper I describe the testing of just one article, so as to make it less complicated.

THE USE OF ELECTRICITY IN PHARMACOŒIAL TESTING.

BY B. I. MURRAY.

Not very much is to be found in current pharmaceutical literature bearing upon the use of electricity for purposes of pharmacopœial testing. Our Pharmacopœia makes no use of electric methods. Our National Formulary, our Dispensatories and practically all of our numerous textbooks used for the instruction of pharmaceutical students contain no references to the use of such methods for testing U. S. P. articles. There appears evidently to be a real lack of what may be termed popular knowledge of the subject among pharmaceutical chemists. This condition is aggravated too by an apparent air of mystery surrounding the subject. As soon as one hears the magic words volt, ampere, rheostat, etc., figuratively speaking the hands are thrown up and we are all at sea. Such a condition of affairs is unfortunate, for be assured electricity is a good and faithful servant, and may be put to use in very many analyses, and indeed in some analyses, where other means fail. Electricity has proved very useful and reliable in the analysis of the chemicals of the Pharmacopœia, not to mention its applicability to the larger number of chemicals used in medicine but not included in the Pharmacopœia.

For those here to-day that may be interested let us describe the analysis of just one article selected from the Pharmacopœia, and exhibit some pieces of apparatus that may be used in miscellaneous work of analysis by electro-methods. The article selected is gold and sodium chloride, and the analysis is made to determine the amount of gold in it.

The assay of Gold and Sodium Chloride for percentage of gold by the hydrogen peroxide method of the U. S. P. VIII being unsatisfactory, it has been found necessary to employ other methods. The peroxide method generally yields low results, but it can be made to work with fair accuracy by repeatedly treating the filtrate from the precipitated gold with fresh quantities of hydrogen peroxide. Even at its best, however, it is not a method to be recommended for use by miscellaneous workers. The method of the U. S. P. VII, reducing the gold by means of oxalic acid, gave
fairly good results, but difficulty was often encountered in filtering out the gold, owing to its extremely fine state of division. Both methods are antiquated, and the method of reduction of the gold by means of formaldehyde in alkaline solution is also thus regarded by some. The latter formaldehyde method is at times unreliable, the gold not fully precipitating. This incomplete precipitation may possibly be due in part to the neutralization of the added alkali by the acid formed in the course of the reaction, and on this account care may well be exercised to keep the alkali in considerable excess. But this method at its best gives unsatisfactory results in the hands of different chemists.

Speaking generally, the electrolytic determination of gold is the modern way. It is unquestionably the accurate method, as well as the elegant method. It is easy and simple to carry out, requiring little if any apparatus not to be found in well-equipped laboratories. No really expensive, unusual pieces of apparatus are required as popularly believed of electro-analysis. (Consult Smith's Electrochemistry for simple forms of apparatus for electro-analysis.)

In general electro-analysis work gold is probably most often deposited from the double cyanide of potassium and gold in the presence of an excess of the cyanide of potassium. The conditions for the precipitation of the gold upon the negative pole are often about as follows: $ND_{100} = 0.38$ amperes, 2.7-3.8 volts, temperature 55°C, time required for gold to precipitate 1.5 hrs., gold present about 0.115 Gm. in 150 Cc. of water containing 1.5 Gm. of potassium cyanide. All the gold in simple gold chloride itself is easily and satisfactorily deposited by the electric current on the cathode by observing these conditions, and it is only necessary to wash and dry it before weighing it. This refers to gold chlorides carrying about forty-five to fifty per cent. of gold and the corresponding quantity of hydrochloric acid.

This operation, gold assay by electrolysis, takes little of the chemist's time and is accurate. To use the older methods in this case (simple gold chloride) especially those methods involving the addition of other metals that have subsequently to be washed out of the precipitated gold on filter paper, is almost inexcusable. Such a method would be the formaldehyde-caustic potash method. The washing of gold deposited by electricity on a platinum surface is very easy.

But as experience shows, this method of determining gold in gold chloride by the use of potassium cyanide and electricity does not work satisfactorily on gold and sodium chloride, which is the U. S. P. article before us. Not all the gold will deposit under any conditions at present known. In preparations of gold and sodium chloride containing thirty per cent. of gold only about twenty-eight to twenty-nine per cent. will deposit, after which the deposited gold discolors and the electrolyte does likewise. The reasons for this failure to entirely deposit are not clear and no modifica-
tion of the conditions of the electrolysis has yet been affected which will cause the remainder of the gold to come down upon the electrode easily and in good condition. It is known, however, that it is the sodium chloride which interferes. This has been demonstrated by direct experiments.

The preferable way, therefore, to determine gold in gold and sodium chloride is to determine it electrolytically in the presence of sodium sulphide. The conditions of this operation are: About 0.15 Gm. of gold and 3.5 Gm. of sodium sulphide in 125 Cc. of water, ND₁₀₀ = 0.2 ampere, 0.75–1.5 volts, temperature 55–60° C. The time required for the gold to deposit is 1.5 hrs. The results are excellent. Smith in his book entitled Electro-Analysis, says that by using a rotating anode the gold may be completely brought down in from seven to twelve minutes and by employing both the rotating anode and mercury cathode this may even be accomplished in five minutes.

There is nothing especially new about this method. It is mentioned here mainly for the purpose of recommending it. It is a reliable method. And in nearly all of the electrolytic assays that may be made upon pharmacopoeial articles there is nothing new, except the application of them to the articles of the Pharmacopoeia. We are lacking many methods of assay of chemicals in our Pharmacopoeia and here is a wealth of carefully proved electrolytic-methods before us, yet untouched by us. It is a serious matter to pass by a field so promising and deprive ourselves of its assistance. To mention a few assays in which electricity is excellent one only needs to enumerate the mercurial compounds, including the quick and accurate determination of the mercury in calomel and in corrosive sublimate. And in the determination of iodine and chlorine in thymol iodide excellent results have been obtained.

The Chairman: We will now pass to the next paper, "On the Importance of Giving the Diagnostic Microscopical Characteristics of Vegetable Drugs included in the U. S. Pharmacopoeia." Professor Schneider is not here, so we will read that paper by title, and proceed to the next one, on the subject of "U. S. P. Melting Point Requirements." This is largely a technical paper reviewing the melting-points in the different Pharmacopoeias. Dr. Menge has for some months past been working on the question, and has tried out a number of methods, and offers here the description of a method which he recommends to be used. As Dr. Menge is not a member of this Association, it will require a motion on the part of some one to accept the paper.

Mr. Stanilaus: I make the motion that the paper be received, and published in the Proceedings of the Association.

Motion duly seconded and carried.

The Chairman: We will now listen to Mr. Dunning's paper, on the subject, "U. S. P. Tests as Reviewed by a Retail Pharmacist."
There are I believe, some druggists who assay some of the vegetable drugs for which assay processes are given in the United States Pharmacopoeia and perhaps test a larger percentage of the chemical compounds—at least test them in part, for I believe that but a small number make a complete examination to the extent of estimating the percentage strength of such compounds as sodium salicylate, potassium and sodium tartrate and I doubt, potassium bromide or iodide and many others.

They are, perhaps, some who make a complete assay or test for a few of the U. S. P. drugs and chemicals, but the large majority rarely if ever make use of these processes.

Several very good reasons account for this condition of affairs, and perhaps one or two reasons not so good. To speak of the latter first, there are no doubt some druggists who are so filled with lassitude—we find this kind of person in every walk of life—that they would not avail themselves of the opportunity to assay their drugs, no matter how good the reason or opportunity for doing so. There are unfortunately a few who could not, who for some reason do not seem to be able to grasp the principle of these processes, and if they could, would not be able to exercise that degree of accuracy necessary for such work; but I honestly believe and know that there are a great number of men in the drug business who do not use these methods of assay, not because they do not thoroughly comprehend them nor because they are unwillingly to devote the time to this necessary work, but because they cannot afford to give the time to it, and moreover in some instances the cost of material used in the assay is prohibitive. An illustration may be offered, extract of opium.

The cost of standardizing an ounce of this extract is but little more for the manufacturing chemist than that of standardizing a hundred or thousand pounds of the drug, and the same statement applies in a greater or less degree to all drugs and chemicals.

This is the reason as many pharmacists know that the requirements of the Pure Food and Drug Laws, the Pharmacopoeia being one of the official standards for same, will result in forcing, in the present condition of the retail drug business, the pharmacist to purchase most drugs requiring standardization from the manufacturing drug concerns including preparations of assayable drugs as tincture of aconite, belladonna, tincture of opium, etc., unless as some will perhaps do, the preparation is prepared from an assayed drug, the final product not being subsequently standardized, thereby risking imperfect extraction of the drug.

I feel certain that the conclusions I have reached in regard to standardized products being largely relegated to the manufacturing pharmacist and, I must confess, that it seems to me both logical and inevitable for obvious reasons.
Regarding my personal opinion as a pharmacist of the U. S. P. tests and assay processes, I believe it agrees in the main with that of most other pharmacists who have given some thought and study to them, or have made use of them.

Personally, I am very proud of the Pharmacopœia as a whole, yet as with everything devised by the human mind it is of course not perfect.

Generally speaking, the tests are not only of high scientific character but are practicable and are within the working knowledge of the educated pharmacist. While some of the tests are tedious, for instance the modified Gutzeit’s test, to insure necessary accuracy they need to be. It might perhaps be well to direct the test to be made for arsenic without previous examination of the chemicals used in testing and in the event of a positive reaction the chemicals used should then be examined.

Methods of determining the iodine and saponification numbers, are, I am inclined to believe, more startling because of the unusual character of these methods than any difficulty in carrying them out practically.

This leads me to suggest that perhaps at times less delicate tests, if less tedious might be applied as preliminary measures; the more delicate tests being applied, subsequently, if necessary.

In regard to the polariscope I believe, to the large majority of pharmacists, it would prove of little value because the occasion for its use would be rare for the same reasons given, in regard to other methods of testing. However, with some study and experience I have no doubt that by many pharmacists the instrument could be used understandingly and with accuracy.

The assay of the volatile oils probably taxes the skill of pharmacists to a greater degree than most other methods of standardization and is a process which they would be last inclined to use. Volatile oils as a rule are substances of no great stability of character and used in exceeding small quantities. The druggist will in rare instances only be justified in assaying or testing them, from a financial viewpoint. However as is true of other assayable products the druggist is glad to feel that, the Pharmacopœia furnishes a proper standard for drugs and chemicals if not for his guidance, then for the man who is his source of supply.

In connection with this discussion I will call attention to several inconsistencies in the tests which were either observed by Dr. Daniel Base, Dr. James Black or by myself.

There seems to me no good reason why dilute hydriodic acid should be estimated by the sulphocyanate method while for dilute hydrobromic acid the “chromate” method is directed.

Different methods are directed for determining the percentage strength and limit of the other halogen salts in the assay process for ammonium iodide and sodium iodide.

While for strontium bromide “chromate” indicator is directed, for the iodide, ferric ammonium sulphate is used.
Copper sulphate test, under calcium or sodium hypophosphite should direct that the solution be acidified.

The test directing the heating of yellow wax with sulphuric acid for the purpose of detecting paraffin or cersin should either be eliminated or modified. Twenty per cent. paraffin can scarcely be detected by the test, for the carbonized wax holds the paraffin and prevents its separation. However, if black residue, after heating with sulphuric acid, be washed and dried and extracted with chloroform or some other suitable solvent then on evaporation paraffin or cersin will be obtained.

The test for cane sugar in sugar of milk, by sprinkling some of the specimen on sulphuric acid is not at all delicate. A much better test is as follows:

Put about one grain of sugar of milk in a small porcelain dish and add ten to twenty drops of a solution containing resorcin and hydrochloric acid in 90 per cent. alcohol, tilt the dish, hold in a Bunsen flame and again tilt the dish so that the solution is no longer in contact with the heated part of the dish: a beautiful vermilion blush will appear in the presence of a small percentage of cane sugar.

**The Chairman:** We have another paper along practically the same line, by members of a special committee of the Scientific Section of the Philadelphia Branch of the American Pharmaceutical Association—a real live body with a long name. This Section has done considerable work along the line of chemical assays of the U. S. P., and Dr. Rosengarten will read the report.

Mr. Rosengarten here presented the report.

**THE CHEMICAL ASSAYS OF THE U. S. P. VIII.**

BY W. GRAHAM, D. W. HORN AND GEO. D. ROSENGARTEN.

At the meeting of the Scientific Branch of the Philadelphia Section of the American Pharmaceutical Association on Friday, February 10th, of this year, a committee was appointed to consider the chemical assays of the U. S. P. VIII.

The committee has reviewed the methods from the points of view of the manufacturing chemist and the analytical chemist. The manufacturing chemist is deeply concerned in the assays because the U. S. P. is the legal standard to which his products must conform. The analytical chemist is concerned, since he is called upon to determine whether or not the products of the manufacturer meet all the requirements of this standard.

It will be readily appreciated because of the responsibility the manufacturer assumes for his products, that efficient analytical laboratories must be maintained by him, and in consequence skilled analysts are required to complete such an equipment. Therefore, as far as methods of analyses are concerned, those interests preponderate which pertain to laboratories fitted especially for analytical work.
The committee has reviewed in detail every assay of chemicals in the U. S. P. VIII., and has endeavored to give their conclusion, as constructive criticism, in the following lines.

The U. S. P. VIII. in general directs that a definite quantity of liquids, for example, 10 Gm. acetic acid be weighed for analysis. This we regard as impracticable and not in accord with the practice of analysts. The extreme difficulty of weighing off exactly a stated weight of any substance is very much increased in the case of liquids as a result of their vapor pressures. In all cases the time consumed in an endeavor to obtain an exact weight is, in our opinion, entirely out of proportion to any advantages to be gained in so doing. In fact, the time consumed in weighing off 10 Gm. of acetic acid exactly is more than should be required for the entire assay. Such a method of procedure would rarely be entertained in general practice, for its requirements are unreasonable and unnecessary.

Further, in directing this method of procedure, the U. S. P. VIII. is not consistent. Elsewhere it clearly recognizes the advantages of the more rational method, and directs the use of the same. Thus, under acid acetic glacial the directions are:

"Introduce into a stoppered weighing bottle 3 Cc. glacial acetic acid, and weigh accurately."

The reasons for the use of this method in cases of strong mineral acids, are of course eminently obvious, and we cannot conceive any objection to its adoption for the assay of all pharmacopoeial liquids.

The same general principle should also be applied in the assay of pharmacopoeial solids. This has been recognized in the directions given for the assays of potassium hydroxide and sodium hydroxide. But in the cases of some other very deliquescent solids, the U. S. P. VIII. directs the method of procedure to which we have raised the above objections. These objections are just as well founded for solids as for liquids. In the assay of strontium iodide the directions are to weigh off 0.5 Gm. of this salt and it can be easily recognized that under atmospheric conditions which frequently prevail, it is practically impossible to weigh satisfactorily and accurately an exact quantity of the chemical in question. We would urge in the interest of accuracy and economy of time the adoption of the general method of procedure for assay as given under the strong mineral acids and alkali hydroxides. If adopted, it would also introduce a greater consistency in pharmacopoeial assays, a result which would be highly desirable.

The work of recalculation necessitated by such a change as we advocate, though great, need not be considered a serious obstacle, for the international atomic weights will undoubtedly be adopted, and recalculation will be necessary in any event.

Since the U. S. P. is now a legal standard, we believe that in revising the methods already given, the most modern and exact methods should
be selected rather than those whose chief advantage is simplicity. The method selected should not be the one best adapted to the analyst, or to his equipment, but the best of all known methods for its particular analytical purposes. It would indeed be satisfactory if this requirement were met by all the volumetric methods of the U. S. P. VIII., but in those instances where this is not the case, the best methods available should be selected to replace those which are used at present.

Wherever the purity rubric is given, and where no method of assay appears in the U. S. P. VIII., the selection of a suitable method is urgently demanded. As we have already endeavored to emphasize and we believe we cannot urge it too strongly, these selections should be made from the point of view of analytical efficiency.

Volumetric methods are said to be more rapid and more simple than other methods. This, however, is only true where a considerable number of assays must be made at frequent intervals;—where a single assay must be made, and that only occasionally, these advantages are often lost on account of the deterioration of the volumetric solutions. Some other form of assay may involve less manipulation and require less time than would be used in getting the solutions ready, and standardized, for the corresponding volumetric assay.

In the preparation of samples for assay, in every case the Pharmacopoeia should specify definite conditions under which the sample must be prepared for weighing. This is, undoubtedly, more important in the cases of salts containing water of crystallization, but the surface properties of the various chemicals differ so widely, that the statement of definite conditions seems available in all cases.

It seems to us inconsistent to standardize a potassium hydroxide solution, using phenolphthalein as an indicator in the standardization, and employ this volumetric solution later in assays where methyl orange is recommended. Since methyl orange acts more satisfactorily in passing from alkaline to acid, and phenolphthalein more satisfactorily in passing from acid to alkaline, an error must be expected amounting to not less than 1.5 Cc. \( \frac{N}{100} \) solutions, under the most favorable conditions when the same solution is used with the two different indicators. Ref. Trommsdorff's Table, Cohn's "Indicators and Test Papers."

Because methyl orange is used directly in cold solutions, and is not sensitive to carbonic acid, boracic acid and silicic acid, we would urge its use when possible, as preferable to phenolphthalein or litmus. As an example of its ready application sodium borate could be assayed directly by solution in an excess of acid, followed by back titration, using methyl orange indicator.

Potassium bitartrate as the basis for alkalimetry and acidimetry is now generally being replaced for good reasons by sodium oxalate, potassium tetroxalate, oxalic acid or constant boiling hydrochloric acid. (See Hulett J., American Chemical Society.)
We believe an endeavor to reduce the number of methods used would be desirable in all cases, where accuracy would not be diminished. It would also be very desirable that all salts of one and the same class, should, if possible, be assayed by one and the same method—for example, potassium iodide is assayed 'by Mohr's method, and strontium iodide by Volhartd's—while under ammonium iodide no assay is given, whereas all these salts might just as well be assayed by one method. This remark also applies to the assay of salts of organic acids, as in the instance of lithium and strontium salicylate. Lithium salicylate being assayed by the use of anhydrous ammonium sulphate, while the strontium salt is determined by the use of sulphuric acid. We would recommend, therefore, that a uniform method be adopted for the assay of such organic salts where, upon ignition, there is no possibility of reduction to the metallic state.  

In conclusion we beg to state that the remarks concerning these various points are made only for the purpose of rendering possible assistance in the approaching task, and for eliminating variations, making all methods of chemical assay efficient, and reducing the factor of personal equation to a minimum, so that there may be brought about as perfect a condition as possible, in order that concordant results may be attained.

**The Chairman**: Gentlemen, the two communications are now before you.

**Mr. Vanderkleef**: It seems to me that the recommendations of this committee, as read by Dr. Rosengarten, are peculiarly pertinent at this time; for this particular reason; that those who are constantly testing substances, as to their conformity to U. S. P. requirements, actually do make use of these suggestions mentioned by Dr. Rosengarten. For example, in standardizing solutions it is absolutely necessary to standardize your solution with the aid of the same indicator that is to be used later in the determination. If you do not, you will get varying results. Now if it is true that there are those who by long experience have learned those facts, why not make those things clear in the Pharmacopoeia, so that those who have not had so much experience, and who use the Pharmacopoeia as a guide, will not be misled, but be properly led along the right lines?

**Mr. Puckner**: A considerable portion of the remarks of Dr. Rosengarten merely show that in the last revision of the Pharmacopoeia, there was a great deal of inconsistency. If the lightning strikes any of those present here, and they be put on the Revision Committee, I hope they will bear that in mind, that most of the criticisms of the Pharmacopoeia are merely of lack of consistency. It is not that the Revision Committee did not know any better. Every now and then it creeps out that they did know better—that they applied the proper procedure in one case, and then forgot it; or, rather, one committee, or one member, formulated the proper procedure, and it was not carried out. If you will analyze the criticisms that have been made of the Pharmacopoeia, I think nearly fifty per cent. of them can be ascribed to lack of proper editorial work; that is, of allowing things to creep in here and there, where a proper review of the whole book would have prevented; and I hope that the future members of the Revision Committee will take this to heart, and bear it in mind, that that is one of the chief things that will have to be considered, that the book must be consistent.
MR. LYONS: I will say that we on the Revision Committee, are very sensible of these imperfections, and that it is certain that another committee will endeavor especially to overcome the great difficulty that results from a committee of twenty-five endeavoring to edit one work. That is really the cause of many of these inconsistencies. After the work is two-thirds finished, some new important modification of a very simple process is introduced, and appears only in one or two or three places in the book, and has not been generally introduced. It is certain that in the new revision there will be more consistency.

MR. REMINGTON: I am more than willing to bear my proportion of the responsibilities of the Pharmacopoeia inconsistencies. It may not be amiss to point out how one of the grossest inconsistencies mentioned this morning, came about. It is a bit of inside history, which I think I may give away at this time. It was at the Atlantic City meeting that Dr. Lyons will remember I raised a protest against just the thing Dr. Rosengarten has pointed out in his paper, about weighing definite quantities. I protested not only because it was against the practice of chemists generally, to do such a thing, but I also protested as a teacher, and pointed out that when we came to use the new Pharmacopoeia as a text-book, we would have to say not to do so and so. The protest was effective, to the extent that certain changes were made. I know there was considerable indignation at the time, so that I went for a solitary plunge, in order to give my colleagues an opportunity to vent themselves.

MR. TURNER: It seems to me that all these criticisms of the Pharmacopoeia could have been made before it was published, and that some method could be adopted by which suggestions for the Pharmacopoeia could be sent out, at least to those vitally interested in the methods, for criticism, before adoption. The Branches could discuss the points, and a majority of the members could very well see the inconsistencies of methods not only in testing the chemical products, but the chemical products, but the volatile oils and clinical preparations; then there would not be as many criticisms as there are now. Moreover, I believe we would have one of the best Pharmacopoeias in the world. The German Pharmacopoeia has adopted that system now.

MR. ELDRED: In connection with what Dr. Rosengarten said, it seems to me that it would be very well to eliminate a large number of the pro-forma solutions that are now given in the Pharmacopoeia. I doubt very much if there is any laboratory that keeps those solutions made up and standardized. Many of them are introduced, and are used for very many assays, and it seems to me that instead of trying to multiply these solutions, an effort should be made to reduce the number to the lowest limit, and make those applicable to as many assays as possible, and not use a different solution for different chemicals and different assays, unless it was absolutely necessary. Then it would be a comparatively simple matter to keep all those solutions in the laboratory, and keep them standardized so that they would be ready at any time.

MR. MURRAY: As to those inconsistencies, we found out from the remarks of Dr. Lyons how a part of them arose, and I think it would be a good idea to have one member of the Committee do the editing, and the others assist in the formation of the new Pharmacopoeia. The present book certainly shows a lack of editing—cross references and all such things are very unsatisfactory.

THE CHAIRMAN: I am afraid that Mr. Murray’s suggestion is rather impracticable. I doubt very much indeed whether one man could do the editing for the several portions of the book; but it certainly would seem as though it were perfectly practicable to have the chairmen of the several sub-committees made responsible for their particular work, and make them the editors for the tests and descriptions in their particular line; and if
this were done, I am pretty sure that each of the chairmen of the sub-committees would see that his portion of the work was edited pretty thoroughly.

**Mr. Turner:** I will offer the following resolution:

"Resolved, That the Scientific Section of the American Pharmaceutical Association recommends to the Pharmacopœial Revision Committee, that in order to promote the efficiency of the Pharmacopœia, and bring it to the highest standard possible, proposed changes in the Pharmacopœia shall be submitted to the members of the American Pharmaceutical Association."

**The Chairman:** I would like to call the attention of Mr. Turner to the fact that we, as the Scientific Section, are not able to pass resolutions; we can recommend it to the Association.

**Mr. Turner:** I will make it then that this Section suggest, or recommends to the General Association that it adopt such a resolution.

**Mr. Kremers:** I think Mr. Turner means the important changes.

**The Chairman:** Yes; let the resolution read that all important changes be given publicity.

**Mr. Schlotterbeck:** The recommendation is a very good one, but does not provide for any way of putting these suggestions before the Association. If these things can be copyrighted I think it would be better to put them in the pharmaceutical press, where they will not only meet the attention of the members of the Association, but of all who are interested in that general line.

**The Chairman:** I would suggest that the Committee on Revision have it in their power, if they so desire, to publish the matter in the form of printed bulletins, and these printed bulletins could be copyrighted, and then sent out to any one who is willing to pay a sufficient sum to cover the expense. I believe that is a perfectly feasible plan, and any man who is interested in the revision of the Pharmacopœia will pay the expense of getting the bulletins, and if he does not offer his criticisms he is partially responsible.

**Mr. Kremers:** So much has been said of publication and greater publicity in the last two years, that I would like to call attention to the fact that there has been at least a little publicity in the past. As far back as 1880 the committees made use of printed drafts of the Pharmacopœia, and I know from members of the committee at that time that they got a great deal of benefit from those printed drafts. The Swiss Pharmacopœia has done the same thing in recent years. As far as our own committee is concerned I would like to point out to those interested that as Chairman of the Committee on Volatile Oils I took every opportunity to collect data on the oils that were to be official for 1900. I brought them together and distributed them at my own expense, to every manufacturer of volatile oils in this country and abroad; and I will say that at that time I got a good deal of "cussing" for my publicity. There were one or two who gave me the benefit of their criticisms, and I was obliged to them for it. Some of the worst things in the Pharmacopœia about volatile oils were things demanded by so-called manufacturers. Some of them were due to bad editing, I will admit, but there were some others put in there because the manufacturers wanted them put in. They thought the Pharmacopœia was a very inoffensive book at that time; that it did not do any harm, and suited a certain demand.

**The Chairman:** The question Mr. Schlotterbeck brings up would be covered by the provision that the Chairman of the Revision Committee be empowered to solicit criti-
cisms from these manufacturers; but all the general changes should be brought to the attention of the people interested, and every one given an opportunity to point out the shortcomings, and then make the chairman of the individual sub-committee responsible for adopting, or not adopting, the changes suggested. He must be the referee. Will the Secretary read the resolution as amended?

Mr. Clark: "Resolved, to submit to the general session of the American Pharmaceutical Association, the recommendation to the U. S. P. Revision Committee, that in order to promote the efficiency of the U. S. Pharmacopoeia IX, and to bring to it the highest standard possible, the proposed important changes should be given publicity by submitting them in printed or some other form, to the members of the American Pharmaceutical Association."

The Chairman here put the motion, and it was unanimously carried.

The Chairman: We now have a paper by Mr. J. R. Rippetoe, "Laboratory Notes on the Pharmacopoeia." If Mr. Rippetoe is not here, we will read the paper by title, and pass on to the next one, which is by Professor Clark, "On the Keeping Qualities of Some Standard Volumetric Solutions."

Mr. Clark: This paper deals more particularly with statistics, and I will briefly review the principal facts regarding the work I have done on this subject. It is a continuation of the work I published last year. In that paper I gave a series of figures showing the changes in titre of some volumetric solutions which had been kept for some time and these figures apply to the same solutions. I still have these same solutions, and this paper simply shows the strength of the solutions at present, as compared with their strength a year ago.

ON THE KEEPING QUALITIES OF SOME U. S. P. VOLUMETRIC SOLUTIONS.

A. H. Clark.

As a continuation of the work presented last year on this subject I offer the following data on the same volumetric solutions as before. In the case of the Tenth Normal Sodium Thiosulphate V. S., the work has been extended somewhat.

TENTH NORMAL SODIUM THIOSULPHATE V. S.

Solution No. 6C.

This is one of the solutions containing alkali reported on last year.

Factor. 1.0121 0.9960

Remarks.—This shows that in spite of the alkali this solution is steadily losing its titre.

From the experiments detailed last year it appeared that the decomposition of a tenth-normal solution of sodium thiosulphate was due, in a measure, to the exposure to light or air, and that the presence of alkali retarded the decomposition to some extent. On the assumption that the decomposition was due to an oxidation of the sulphur some experiments were started in which reducing agents were added to the solution, and also the experiments with alkali continued.
A solution was prepared approximately tenth normal, from "C. P. Granular" sodium thiosulphate and distilled water. This solution we will call solution No. 9.

**Solution No. 10.**

Method of preparation.—To 1000 Cc. of solution No. 9 was added 10 Cc. distilled water.

Method of preservation.—In a clear glass, cork-stoppered bottle.

Factor. 1.0504. 1.0373.

Remarks.—This solution showed a decided flocculent precipitate.

**Solution No. 11.**

Method of preparation.—Same as No. 10.

Method of preservation.—In an amber-colored bottle with cork stopper.

Factor. 1.0504. 1.0352

Remarks.—Shows a decided flocculent precipitate. Titre decreased the same as No. 10. Evidently the protection from light afforded by the amber bottle was of no value.

**Solution No. 12.**

Method of preparation.—To 1000 Cc. of No. 9 ten Cc. fifth-normal sodium hydroxide V. S. was added.

Method of preservation.—Same as No. 10.

Factor. 1.0504. 1.0417.

Remarks.—No signs of decomposition in this solution.

**Solution No. 13.**

Method of preparation.—To 1000 Cc. of No. 9 add ten Cc. half-normal sodium hydroxide V. S.

Method of preservation.—Same as No. 10.

Factor. 1.0504. 1.0373.

Remarks.—No sign of decomposition in this solution.

**Solution No. 14.**

Method of preparation.—To 1000 Cc. of No. 9, add ten Cc. normal sodium hydroxide V. S.

Method of preservation.—Same as No. 10.

Factor. 1.0504. 1.0417.

Remarks.—Considerable precipitate. Apparently the alkali had attacked the glass. It seems from these experiments that the addition of alkali while preventing the formation of a precipitate, did not retard the decomposition of the solution as far as its titre was concerned, as this decreased in solutions No. 12, 13 and 14, about as much as in Nos. 10 and 11.

Those solutions to which "preservatives" were added (a small quantity of thymol, resorcinol, formaldehyde, etc., to act as reducing agents) did not retain their titre any better than those with alkali or nothing present.
The same solution as reported on last year.
Factor. 1.0419 1.0450
Remarks.—This solution is now about two years old and is of the same titre as when first made.

The same solution as reported on last year.
Factor. 0.9341 0.9305
Remarks.—The titre of this solution has not changed in sixteen months.

The same solution as reported on last year.
Factor. 1.0148 1.0188
Remarks.—This solution is now two years old and is of the same factor as when first made.

The same solution as reported on last year.
Factor. 1.0653 1.0640
Remarks.—This solution is now nearly four years old and is of the same factor as when first made.

The same solution as reported on last year.
Factor. 1.0823 1.0800
Remarks.—This solution is now about sixteen months old and of the same factor as when first made.

University of Illinois School of Pharmacy, Chicago, Ill.

Mr. Asher: You make mention of the titre of these solutions being unchanged. I do not quite understand this as I see some difference in the figures as given by you. Will you kindly explain this?

Mr. Clark: I pointed out last year that a change of four points in the third decimal, means a difference, in titrating 25 Cc. of one solution against 25 Cc. of another of only one-tenth of a Cc. in the reading: so as I said then I consider the solution has not changed in strength if the change in factor is not more than four points in the third decimal place.

Mr. Brown: I have had some experience in making thiosulphate solution; we make up enough to last six to eight months, and I had a great deal of trouble in keeping my
thiosulphate for some time, but I found by boiling my distilled water before making up the standard solution, that the titer did not change more than four places in the third decimal, in six to eight months. I have heard it suggested that chloroform will preserve thiosulphate solution; however, I have never tried it.

Mr. Clark: I had one solution that kept for nearly three years without the slightest change. I did not know at the time how it was made, so I did not report on that.

The Chairman: The next paper on our program was by request presented yesterday afternoon. Mr. Moerk is not here, so that his paper, "The Volumetric Calculations of the U. S. P." will be passed by title. Mr. Kremers has several communications which he desires to bring before you.

Mr. Kremers here presented the following paper, accompanying his remarks with blackboard illustrations.

REVISION OF CYMENE AND ITS OXIDATION PRODUCTS.*
From the Laboratory of Edward Kremers.

THE HIGHER OXIDATION PRODUCTS OF THYMOQUINONE.
By Nellie Wakeman.

In the phytochemical study of the monardas that has been carried on more or less continuously in this laboratory for the past fifteen years the chemist has always been baffled by certain residues. Every distillation and every recrystallization has left a residue that has defied attempts to crystallize it or to separate it in any known manner. Sometimes these residues have taken the form of a heavy oil, varying in color from red, through purple or brown to black and sometimes they have formed tarry masses. Whatever the color or the consistency of the residues, however, they have always had many properties in common, the most noticeable of which have been their behavior toward solvents and alkalies. Insoluble in water but very soluble in all other ordinary solvents, they have offered no encouragement to attempts to separate them by differences in solubility in different solvents. When touched with alkali the same deep red-purple solution has always been obtained, no matter what the alkali or the strength of the solution.

In her study of thymoquinone† and hydrothymoquinone (1908) the writer met with residues that resembled in every way those encountered in the study of the monardas. Since the greatest amounts of these resi-

* The papers thus far published are herewith recorded. Others are in preparation.
† Ph. Rev., 29, p. 329, 364.
dues were obtained when oxidation had been carried too far, she was led to a study of the oxidation products of thymoquinone. In the course of this study it was learned that dihydroxythymoquinone corresponded with the red crystals obtained by Mead* (1895) and later by Suzuki † (1905-06).

Therefore, when a small quantity of the same red crystals was separated from a monarda residue, it seemed that a least a beginning had been made on these hitherto seemingly hopeless mixtures.

At the time that the red crystals were first obtained in the distillation of the oil from Monarda fistulosa the statement was made that this was the coloring matter ‡ which gave the red or brown color to some of the oils. Later, when thymoquinone and hydrothymoquinone § were separated from the monarda oils and the quinhydrone hypothesis of plant pigmentation was formulated, it was supposed that the color of the dark oils, as well as the purple pigmentation of stem and flower was due to thymoquinhydrone. More recent studies have led us to believe that both suppositions were correct.

In order to appreciate the capacity of hydrothymoquinone and its oxidation products to produce pigments, one must take into consideration the structure of these compounds and their possibilities for reaction, forming not only quinhydrones but phenoquinones and polythymoquinones, with each other and with themselves. Starting with cymene, the underlying hydrocarbon, we have the following remarkable series of compounds, all but one of which have actually been isolated from the monardas. That one, rather the two isomeric oxythymoquinones, while it has never actually been isolated, has been indicated, again and again, in the alcoholic extracts from the plant, in the oils, and in the residues.

* Ph. Rund., 13, p. 207.
‡ Ph. Rund., 13, p. 207.
§ Ph. Rev., 19, p. 200.
Besides these simple compounds, as stated above, there are the pheno-quinones, quinhydrones and polyquinones, any or all of which may be expected to occur in the oils, or at least in the residues.* To get an idea of the capacity for forming these complex compounds let us consider one of the simple compounds, the dihydroxythymoquinone. As will be seen from the foregoing chart, this compound is not only a quinone but a diatomic phenol and possesses, theoretically at least, all the possibilities for reaction possessed by both classes of compounds. As a quinone it can form quinhydrones with hydrothymoquinone and with itself. As a diatomic phenol it can form them with thymoquinone and oxythymoquinone. It can form phenoquinones with thymol, carvacrol, and with oxythymoquinone. And it can form polyquinones with thymoquinone, oxythymoquinone and with itself. When we add to these compounds those theoretically possible by combining the other compounds in the chart with each other and with themselves, we have an array of formulas that is truly formidable, not only in number but also in complexity.

With these possibilities in mind one still marvels, it is true, at the varied tints of stems, flowers, and leaves; but it is with a feeling of satisfaction and appreciation. And when one sees the color change as the relative amounts of the different substances are changed in mixtures, one realizes more than ever that the rapid changes in the colors of leaves in autumn cannot be explained as a mere breaking-down of chlorophyll.

**Occurrence in Plants.**

_Dihydroxythymoquinone._—In 1895 Mead † in distilling a small quantity of phenols, separated from the oil of _Monarda fistulosa_ by alkalies, obtained red crystals which sublimed in the condenser and were collected separately. The crude crystals melted at 219-223° C., and gave a purple color with alkalies. Sublimed between watch glasses the scarlet-red prismatic crystals melted at 256-266° C. In 1905-6 Suzuki ‡ in the same way obtained a small quantity of the same red crystals and studied their properties. He found them soluble in strong hot alcohol and in ether, sparingly soluble in hot water with a red color, soluble in aqueous alkalies with a purple color. Recrystallized from strong hot alcohol, they melted at 225-226° C. Some of these crystals tested by the writer yielded with lead acetate the green precipitate characteristic of dihydroxythymoquinone, as did also these separated by Mead.

Suzuki points out the fact that residues of different colors were obtained in the various methods employed for purification, and concludes that the

* Since writing the above, dithymoquinone has been obtained in quantity in the process of rectification of thymoquinone from _Monarda fistulosa._

† _Ph. Rund.,_ 13, p. 207.
needle-shaped crystals deposited on the inner tube of the condenser may have been a mixture of several substances. This view is probably correct. The fact that dilution of the alcoholic mother liquor with water yielded a voluminous white precipitate (like the precipitate of hydrothymoquinone from aqueous solutions) and that the pink solution obtained by boiling the impure crystals with water left a white residue, leads one to suspect the presence of hydrothymoquinone. This hydrothymoquinone presumably was combined with the dihydroxythymoquinone in the form of a quinhydrone. Another residue, insoluble in ether, was of a purple color. Suzuki's crystals, moreover, when turned over to the writer were of two kinds, one a bright cherry-red, the other dull purple-red in color. The quantities, however, were too small to be used for more than a few preliminary tests.

A short time ago it was found that crystals of dihydroxythymoquinone had spontaneously sublimed from a residue obtained from the phenol portion of a Monarda oil, that had been left in a large flask after distilling. These crystals had collected on the walls of the flask and on the upper surface of the tarry residue. After being removed by washing out with petroleum ether they responded to the tests for dihydroxythymoquinone. Red crystals also separated upon standing from the carvacrol obtained from M. fistulosa. These crystals were filtered out and found to be dihydroxythymoquinone.

Since dihydroxythymoquinone has been prepared by shaking thymoquinone with caustic alkali; * and since the phenol oil from which all this dihydroxythymoquinone has been isolated, was separated from the original oil by shaking with caustic alkali, the question arises: was the dihydroxythymoquinone actually present in the plant, or was it produced by shaking a thymoquinone-containing oil with caustic alkali? Aside from the fact that the five per cent. solution of alkali used in separating the phenols seems scarcely sufficiently strong to produce the oxidation, there is nothing to prevent our supposing such may have been the case. We have, however, indications of dihydroxythymoquinone in plants where there can be no question of its having been thus formed.

In 1832 Elsner † extracted the pigment from the corollas of Monarda coccinea (M. didyma L.) and found the dried pigment to be of a purple-red color. Tested with basic lead acetate in aqueous solution, it gave a bluish-green precipitate, one of the characteristic tests for dihydroxythymoquinone. The writer obtained this precipitate from the alcoholic extract of Monarda didyma corollas with both basic and normal lead acetate, and also the characteristic pale violet color with lime water. These reactions were obtained also from the aqueous solution obtained by dissolving

---

* See the experimental part of this paper.
the dried alcoholic extract of the pigment from both the purple stem and the red autumn leaves of *Monarda fistulosa*.

**Monohydroxythymoquinone.** — As stated above monohydroxythymoquinone has never been isolated from a plant or a plant product. Elsner obtained a violet-red precipitate from the aqueous solution of the dried pigment of *Monarda coccinea* (*M. didyma*) when treated with normal lead acetate. This violet-red color with lead salts has been found by the writer to be characteristic of monohydroxythymoquinone. It has been obtained repeatedly from the residues of *M. fistulosa* and *M. punctata*, also from the phenol portion of the oil from *M. citriodora*, *M. fistulosa*, and that portion of the phenol oil of *M. punctata* that did not solidify when chilled below zero.

Not only from the evidence of these tests but also from the position of the oxythymoquinones in this series of compounds does it seem reason able to suppose that monohydroxythymoquinone is present in the Monarda species along with the other members of the series. The fact that it is almost impossible to prepare either thymoquinone or dihydroxythymoquinone without obtaining at least traces of the monohydroxy compound lends weight to this supposition. And when we take into consideration the unsettled state of the chemistry of the monohydroxythymoquinones, owing, no doubt, to the existence of the two isomeric forms no less than to the difficulty with which they are separated from the mixtures of thymoquinone and dihydroxythymoquinone with which they always occur, it seems in no way remarkable that, if present in the plants, they have not yet been isolated.

\[ \Delta 3,6 \text{ Terpadiene-dione-2}, 5, \text{-ol 6} ; \text{and} \ \Delta 3,6 \text{ Terpadiene-dione-2}, 5, \text{-ol 3}. \]

**Synonyms.**—Oxythymoquinone. * Hydroxythymoquinone. † Oxythymoile. ‡

**History.**—Oxythymoquinone was probably first prepared by Lallemand § in 1857. In studying the effect of light upon thymoquinone, he exposed it to bright sunlight in sealed tubes and obtained a black product which, upon washing with alcohol, yielded a yellow powder while the alcoholic solution contained a mixture of thymoquinone and thymoquinhydrone. This crystalline powder, which was only a small fraction of the material employed, was also found in the products of distillation of thymoquinone from which it was separated by washing with alcohol. Lallemand describes this product as insoluble in water and alcohol; also in alkalies and indifferent to nearly all reagents; soluble in ether; m. p. 190°C. By

* Jr. pr. Ch., III, p. 50.
elementary analysis Lallemand obtained the formula \( C_{22}H_{16}O_6 \) (thymoquinone \( C_{22}H_{16}O_4 \)); hence concluded that it was thymoquinone that had taken on two equivalents of oxygen, and named it oxythymoile, from thymoile as he called thymoquinone. The record of this experiment is doubly interesting because it shows that one of the earliest observed properties of thymoquinone was that which we now call autoxidation, the power of reducing one molecule to oxidize another.

No further mention of oxythymoquinone is found in chemical literature till Carstanjen, * in 1871, prepared it from monobromthymoquinone and from the diamidothymol dihydrochloride. Then, in 1877, comes a long discussion between Ladenburg and Engelbrecht † Liebermann, ‡ and Carstanjen § about the melting point of the compound, its true structural formula, and the possibility of there being two isomeric forms satisfying the same empirical formula. This discussion is continued by Zinke || in 1881 and by Schulz ¶ in 1883. Finally, in 1890, Mazzara ** differentiates between two oxythymoquinones with different colors, forms of crystals and melting-points to distinguish them, calling one (a) or 6-oxythymoquinone, and the other (β) or 3-oxythymoquinone.

Methods of Formation and Preparation.

I. From monobromthymoquinone.

In 1871 Carstanjen ‡‡ prepared oxythymoquinone by dissolving monobromthymoquinone in warm potassium hydroxide solution in which it dissolves with a dark red-brown color. From this solution it was precipitated with dilute acid as a flaky yellow powder. After drying it sublimed in beautiful scarlet crystals.

II. From diamidothymol.

(a) Carstanjen, §§ in 1871, prepared oxythymoquinone from diamidothymol dihydrochloride (obtained from dinitrothymol) by distilling with platinum chloride.

(b) By distilling with ferric chloride, in 1877, Liebermann || obtained oxythymoquinone from diamidothymol, obtained from both nitrosothymol and thymol sulphonic acid through the dinitrothymol.

(c) Ladenburg ¶¶ and Englebrecht, in 1877, prepared oxythymoquinone by distilling with steam ferric chloride and damidothymol, obtained from dinitrothymol through the ethyl ester.

(d) In 1890 Mazzara *** prepared the compound which he

---

* Jr. pr. Ch., 111, pp. 57, 58. † Ber., 10, p. 1219.
‡ Jr. pr. Ch., 123, p. 399. ‡ Ber., 14, p. 97.
called (a)-6 oxythymoquinone by distilling diamidothymol dihydrochloride (obtained from dinitrothymol) with ferric chloride.

III. From dinitrochlorcymene.

(a) In 1877 Ladenburg* and Englebrecht obtained oxythymoquinone from dinitrothymol, through dinitrochlorcymene.

IV. From diamidocarvacrol.

By distilling diamidocarvacrol hydrochloride with ferric chloride, in a current of steam, Carstanjen,† in 1877, prepared oxythymoquinone.

V. From dinitrocarvacrol.

In 1890 Mazzara‡ prepared β-oxythymoquinone by reducing dinitrocarvacrol and oxidizing with ferric chloride.

VI. From thymoquinone.

1. Zincke,§ in 1881, prepared oxythymoquinone by treating thymoquinone with methyamine and hydrolizing the resulting methylamido compound by boiling with dilute hydrochloric or sulphuric acid.

2. In 1883 Schulz¶ prepared oxythymoquinone by treating thymoquinone with dimethyamine, thus securing the dimethylamido compound which he hydrolized as above.

3. In 1857 Lallemand¶† obtained oxythymoquinone by autoxidation by exposing thymoquinone to light in sealed tubes.

VII. From dioxythymoquinone.

In 1881 Zincke** obtained oxythymoquinone by reducing dioxythymoquinone with sulphurous acid, then oxidizing with ferric chloride.

Purification. Lallemand purified oxythymoquinone by sublimation, also by recrystallizing from hot alcohol; Schulz by recrystallizing from hot water or from dilute alcohol; Mazzara by recrystallizing from hot alcohol.

Physical Properties. Form, color, melting-point.—There are many conflicting reports as to the form of crystals, color and melting-point of oxythymoquinone, probably due to a confusion of the two isomeric forms and to the fact that a mixture of oxy- and dioxy-thymoquinone has been mistaken for pure oxythymoquinone. Castanjen describes oxythymoquinone as existing in regular rhombic scarlet-red crystals, m. p. 187° C.; also as orange-yellow crystals, m. p. 165–166° C. Lieberman†† describes the crystals as orange-colored, m. p. 183–185° C.; Zincke‡‡ as orange or brownish-yellow plates and broad needles, m. p. 174–175° C., also as yellow plates m. p. 165° C.; Schulz,§§ as small needles, yellow to yellow-brown, m. p. 166–176° C.; while Mazzara¶¶ says that α-oxythymoquinone exists in

---

** Ber., 14, p. 97. †† Ber., 10, pp. 79, 613. ‡‡ Ber., 14, p. 97.
Solubility.—All experimenters (Lallemand excepted) agree that oxythymoquinone is soluble in hot alcohol and ether, and in alkalies with a violet-red color, while Schulz adds hot water, chloroform, benzol, etc., to the list.

Chemical Properties.—Oxythymoquinone forms salts with the alkalies and with calcium and barium which are very soluble in water with violet-red color. The salts of the heavy metals are insoluble.

The following compounds are given by Beilstein: *

Ethyl ether of oxythymoquinone.
Chloroxythymoquinone.
Aminoxythymoquinone.
Anilineoxythymoquinone.
p. Tolidooxythymoquinone.

EXPERIMENTAL PART.

In addition to the above, much of which has been duplicated by the writer, the following experimental work has been accomplished:

Preparation.—In attempting to prepare the thymoquinone hydroxysulphonate of sodium, as Carstanjen had formed the corresponding potassium salt, by the use of normal sodium sulphite, instead of pale yellow crystals a heavy purplish-red solution resulted. This, upon standing for several days, changed to a thick tarry mass. The mass was dissolved in 50 per cent. sulphuric acid and distilled with steam till the distillate was no longer acid, a large amount of clear yellow acid distillate being obtained. The acid residue in the flask was of a deep wine color. From this, upon standing, orange-red crystals separated. These were collected and recrystallized from strong hot alcohol, yielding orange yellow, small needle-shaped crystals; m. p. 165–166° C.; soluble in hot alcohol, ether, benzene and chloroform, also in aqueous alkalies with a pure purple color.

Chemical Properties—Tests.—The purple-red color with calcium hydroxide and barium carbonate was found to be characteristic for oxythymoquinone, being much more intense than the color reaction with the related compounds.

When treated with normal or basic lead acetate a violet-red solution, or precipitate, is formed depending upon the concentration of the solution.

Quinhydrones.—A solution of oxythymoquinone yields a red color with a solution of fuchsin decolorized by sulphurous acid, as does also a solution of hydrothymoquinone. This color reaction is not given when a solution of molecular quantities of oxythymoquinone and hydrothymoquinone is treated with the decolorized fuchsin solution, thus showing the formation of some compound, probably a quinhydrone.

Traces of a purple quinhydrone have been obtained, also, by evaporating

* Beilstein III., p. 368.
an ethereal solution of molecular quantities of the two compounds mixed. Indications of a quinhydrone formed by the union of oxythymoquinone with dioxythymoquinone have also been obtained, but not sufficiently strong to warrant an assertion of the existence of such a compound under the conditions tried.

\[ \Delta 3.6 \text{ TERPADIENE-DIONE 2, 5, -DIOL 3, 6.} \]

*Synonyms.* — Dioxythymoquinone. † Bioxythymoquinone. ‡ Dihydroxythymoquinone. § Thymozarin. 

*History.* — The first mention of dioxythymoquinone in chemical literature appears to be that of its preparation by Carstanjen in 1871 from dibromthymoquinone by dissolving the latter in hot potassium hydroxide solution and precipitating with dilute acid. Since then it has been prepared and studied along with oxythymoquinone, the two substances usually being formed at the same time. This fact, together with the difficulty with which they are separated, has led to much confusion, and discussion, regarding the properties of the two compounds since mixtures of the two were doubtless often mistaken for pure substances.

*Methods of Formation and Preparation.*

I. From thymoquinone.

In 1881 Zincke prepared dioxythymoquinone from thymoquinone by treating with methylamine, then hydrolizing the resulting amido compound.

II. From dibromthymoquinone.

1. Carstanjen obtained a small yield of dioxythymoquinone by dissolving dibromthymoquinone, moistened with alcohol in hot potassium hydroxide solution and precipitating with dilute acid.

2. Zincke in 1881 obtained dioxythymoquinone by treating dibromthymoquinone with methylamine and hydrolizing with sulphuric acid or hydrochloric acid.

III. From oxythymoquinone.

1. In 1877 Ladenburg and Engelbrecht prepared dioxythymoquinone by boiling oxythymoquinone in potassium hydroxide and precipitating with hydrochloric acid, then crystallizing from hot alcohol.

IV. From chloroxythymoquinone.

1. Ladenburg and Engelbrecht in 1877 prepared dioxythymoquinone from chloroxythymoquinone by boiling with potassium hydroxide, precipitating with hydrochloric acid and crystalizing from hot alcohol.

V. From dinitrothymol.

Ladenburg and Engelbrecht by oxidizing the reduction prod-

---

ucts of dinitrothymoether obtained dioxythymoquinone in an impure condition being mixed with oxythymoquinone.

Methods of Purification.—All authorities agree in purifying dioxythymoquinone by crystallizing from hot alcohol. Zincke * and Ladenburg † say that it sublimes unchanged at temperatures above the melting-point, while Carstanjen ‡ states that when one attempts to sublime it, it chars and only a very small fraction of the original substance is obtained in crystals.

Physical Properties.—Zincke describes dioxythymoquinone as existing in bright red prisms and needles, m. p. 213° C. Ladenburg and Engelbrecht say cherry-red glistening needles, m. p. 230° C.

It is soluble in hot alcohol, difficultly soluble in hot water, soluble in alkalies with a violet color.

Chemical Properties.—When treated with § sulphurous acid at 120–130° C., it is reduced to probably either oxy-or dioxy-hydrothymoquinone, i. e., trihydroxy or tetrahydroxy cymene, which when oxidized with ferric chloride yields oxythymoquinone.

Carstanjen ‡ by heating dioxythymoquinone with ferric chloride obtained bright yellow sparkling crystals (Krystallflitter) which he looked upon as C_{10}H_{10}O_{4} and called-thymodichinon.

Dioxythymoquinone ¶ forms the following salt-like compounds:

Barium compound.—Dark violet or dark green needles and plates, very soluble in water.

Lead compound.—Green precipitate.

Diacetate.—Yellow needles, m. p. 81° C.

Dibenzoate.—Yellowish, thick prisms or needles—m. p. 163° C.

By boiling dihydroxythymoquinone with an excess of potassium hydroxide solution Fichte ** obtained ethyl isopropyl succinic acid.

Dihydroxythymoquinone (Experimental Part).

Methods of Preparation.

I. From dibromthymoquinone.

Dihydroxythymoquinone was prepared according to Carstanjen by moistening dibromthymoquinone with alcohol, then heating with potassium hydroxide. The dark red-brown solution was precipitated with dilute sulphuric acid, the precipitate washed with hot water, then crystallized from hot alcohol. Some red crystals separated out, which melted at 210° C.; when again crystallized from hot alcohol they melted at 216° C. The yield was very small—not more than 2 or 3 per cent., a large amount of black resinous matter being obtained.

II. From thymoquinone and potassium hydroxide.

Five grams of thymoquinone were dissolved, with shaking, in 50 Cc. of a 20 per cent. potassium hydroxide solution and heated on a water-bath for one hour, with occasional shaking; then distilled with

* Ber., 14, p. 95. † Ber., 10, p. 1222. ‡ Jr. pr. ch., p. 62.
** Ann., 361, pp. 376, 397.
steam. A clear yellow distillate with a strong acid odor was obtained. On cooling some red crystals separated, while others condensed in the tube. The crystals from the condenser were bright red, m. p. 220° C. Those separated from the distillate were orange-red and melted at 253–255° C. After recrystallizing from hot alcohol, m. p. 217° C. The two portions were then recrystallized together, m. p. 220–223° C. Again recrystallized, m. p. 225–226° C. Better results were obtained by this method than by the preceding one.

**Purification.**—By crystallizing from hot alcohol.

**Physical Properties.**

**Form and Color.**—Bright red crystals.

**Solubility.**—Insoluble in cold and not easily soluble in hot alcohol (95 per cent.). Very slightly soluble in boiling water.

**Melting Point.**—225°–226° C. Sublimes at higher temperatures.

**Chemical Properties.**—It dissolves in alkalies with purple-red color. With both normal and basic lead acetate a green precipitate is produced; with lime water, a violet color.

The dihydroxythymoquinone gives a bright-red color reaction with a decolorized solution of fuchsine. This reaction is prevented when molecular quantities of hydrothymoquinine or thymoquinine are mixed with the dihydroxythymoquinone solution, showing the formation of compounds, probably quinhydriones, with these substances. The color reaction with fuchsine is also prevented to a large extent when a molecular quantity of oxythymoquinone is added.

In preparing dihydroxythymoquinone by treating thymoquinone with potassium hydroxide a large amount of clear yellow acid distillate was obtained. This acid solution, whose odor strongly suggested a fatty acid, resembled in both appearance and odor the distillate obtained when monohydroxythymoquinone was prepared by the action of sodium acid sulphite on thymoquinone. This distillate was neutralized with barium carbonate and the silver salt prepared from the crystallized barium compound. Silver determinations of the silver salt obtained from two separate distillates gave 55 and 57 per cent. of silver respectively. The silver compound, however, was very unstable and, though filtered and dried in the dark, often turned black before it could be weighed. These results, which may therefore be considered high, were thought to indicate the presence of valeric acid (Ag = 52 per cent.). They might, however, with equal probability, indicate the ethyl isopropyl succinic acid (Ag = 54 per cent.) obtained by Fichter* (1908) upon boiling dihydroxythymoquinone with potassium hydroxide solution.

By boiling oihydroxythymoquinone—with an excess of sodium hydroxide—the ring is broken and ethyl isopropyl succinic acid is obtained.

At the conclusion of Mr. Kremers’ remarks, the program for the morning was completed; but Mr. Raubenheimer, at the invitation of the Chairman, brought to the attention of the Section a bottle containing urine which had developed a peculiar color, which he was unable to account for, and read a paper on the detection of methylene blue in urine, which was discussed informally by Mr. Vanderkleed, Mr. Kremers, Dr. Lyons, Mr. Turner, and Mr. Shimpf, the latter citing a similar case in his experience.

**METHYLENE BLUE IN URINE—ITS DETECTION.**

**BY OTTO RAUBENHEIMER, BROOKLYN, N. Y.**

The writer, a practical retail pharmacist, who prefers to make a urine analysis to the sale of postage stamps, has during this spring encountered
some very curious specimens. Numerous samples of greenish-blue urine were brought into my laboratory by different physicians, who were at first under the impression that the color was due to indigo blue, resulting from the oxidation of indican. This surmise was strengthened by the fact that chloroform extracted the blue color and left the urine almost colorless, as in the tests for indican. However, the patients were not sick, but merely frightened on account of the greenish-blue urine. Furthermore, when the regular indican tests i.e. Obermayer's (HCl + FeCl₃) were applied, then chloroform did not extract color.

For these two reasons there was no indican present. I learned that samples of a proprietary kidney pill had been distributed which contained methylene blue or methylthionine hydrochloride, and to this chemical the color of the urine was due, although some of the patients denied having taken the pills.

Methylene blue taken internally will color the urine green or greenish-blue, or even intensely blue, if taken in large doses. I might also state here that the dye “methyl-blue,” the sodium salt of triphenylpararosanilinethrisulphonic acid will not color the urine, a point well to remember for physicians as well as pharmacists.

For my own satisfaction I made some pharmacological experiments on myself. I found that the internal administration of one and even one-half grain of methylene blue will color the urine intensely green after three hours. The morning's urine, after remaining in the system over night, is very dark blue or greenish-blue, has even a blue foam upon shaking, and upon cooling deposits some of the blue on the sides of the bottle. The color of the urine gradually decreased, but with one grain of methylene blue it lasted 48 hours, and with one-half grain about 24 hours. Samples of the different urines, properly marked, were used for experiments, and upon being set aside developed a very strange phenomenon which will be referred to later.

Although the pharmaceutical and chemical laboratory of the writer is an extensive one, I find that books on urine analysis merely state that the blue color of urine might be due to methylene blue, but neglect to give any distinctive tests for the same. I was therefore compelled to work out tests of my own which might be of interest to members of the Scientific Section of the A. Ph. A.

Indigo blue or indigotin, the hydrolization product of the glucoside indican, is soluble in chloroform, amyl alcohol and nitrobenzene. Methylene blue is also soluble in these three chemicals, and I find that in extracting it from urine the chloroform is colored blue, amyl alcohol bluish-green, and nitrobenzene green. The next edition of the U. S. P. might mention the solubility of methylene blue in chloroform.

While indigotin is also soluble in carbon tetrachloride, an old friend of mine, and which therefore can be used in place of chloroform in the in-
dian tests, I found out that methylene blue is insoluble in CCl₄, which
fact can therefore be utilized as a differential test in urine analysis, etc. The next edition of the U. S. P. might perhaps also mention the insolubility of methylene blue in carbon tetrachloride (difference from indigotin).

Other destructive tests for methylene blue in urine which I have worked out are the following:
1. The addition of hydrochloric acid bleaches the urine.
2. The addition of hydrochloric acid to the blue chloroform layer de-
colorizes same.
3. The addition of sodium hydroxide T. S. (but not of KOH) destroys
the blue or greenish-blue color of the urine.
4. The addition of the same reagent to the blue chloroform layer
changes same to be a violet purple forming methyl violet.

Other distinctive tests for methylene blue in urine and also differential
tests from indigotin will be experimented with and will be reported at a
later date.

Remarkable Phenomena.—As I stated before, the samples of methylene
blue urine were set aside in bottles, corked and numbered. Imagine my
surprise when about two weeks thereafter I found all the samples faded
with the exception of Nos. 1 and 2, the first urination which contained
the largest quantity of methylene blue. Furthermore the urine was not
putrid, but well preserved, showing that methylene blue possesses such
properties. However, my surprise became still greater when after shaking
the bottles and quite especially when admitting air the urine became again
green or greenish-blue as you can see yourselves by this demonstration.

The different tests can be applied to the urine in the same way as to
the fresh samples. After standing a short time the blue or green color
will fade again.

As this is evidently a process of reduction and oxidation which is un-
usual and which I have not seen published before, I take pleasure in
bringing it before the Scientific Section of A. Ph. A. for discussion.

On motion, the Section here took a recess until 3 o'clock, P. M.

Adjourned Session, Friday Afternoon, May 6th, 1910.

The Session assembled at 3 o'clock, Mr. William O. Richtman, Asso-
ciate, acting as Chairman.

The Chairman: Our first paper this afternoon is by Mr. Henry Kraemer,
"The Anatomy of Phlox Carolina."

Mr. Kraemer: I would like to present both of my papers—the one to which the
Chairman has just referred, and another which is down on the program as "A New and
General Adulterant of Foods and Drugs." I will present the latter first.
At the Pharmaceutical Meeting of the Philadelphia College of Pharmacy held November 16, 1909, Mr. E. H. Gane exhibited a sample of "vegetable shells," which he stated were imported probably for the purpose of replacing walnut shells, olive pits, etc., owing to the ease with which these latter products can now be detected when used as adulterants. (See *Am. Journ. Pharm.*, 81, p. 597, December, 1909.)

A preliminary examination of the sample showed that it was composed of the pericarp of some fruit. I then gave the sample to one of my students, Mr. Peter Amsterdam, to study microscopically and in comparison with the pericarps of similar fruits in our collection. This study showed that the material consisted of the hulls, or outer layers of the pericarp, of the fruit of *Juglans regia*, or English walnut, the nuts of which are common in the markets as an article of food.

The hulls (outer portion of the pericarp) of the fruit of *Juglans regia* have been used in the fresh and green condition in medicine, and are described in foreign works under the name *Cortex Fructus Juglandis* (*Cortex nucum Juglandis viridis*. Grüne Walnusschalen. *Brou de noix*). The hulls are described by Vogl in his Pharmacognosy, and a rather extensive article on their histology is given by Hartwich in the *Archiv der Pharmacie*, 66, p. 325 (1887).

**Macroscopic Characters.**—The dried hulls, or "shells," consist of pieces or fragments composed for the most part of the outer layers of the pericarp, the epicarp and sarcocarp. The pieces are more or less irregular, involuted, shriveled, vary from 5 to 35 mm. in diameter, and break with a short fracture. Some of the pieces are marked by the stem-scar or still have attached to them portions of the stem. Externally, the epicarp, or outer layer, is rather smooth, though coarsely wrinkled, marked by numerous small dots, and varies in color from light to dark brown. The sarcocarp, or inner layer, is somewhat spongy, dark brown or blackish-brown in color, and more or less fibrous, due to the shrinking of the parenchyma from the fibro-vascular bundles.

The taste of the hull is markedly acid and somewhat bitterish, but the odor is not very pronounced or characteristic.

**Microscopic Characters.**—The epicarp shows the presence of numerous broadly elliptical stomata (Fig. A) which are from 50 to 70 microns in length; the opening between the guard-cells is large, and sometimes irregular in outline, or the guard-cells may be separated along the adjoining walls, due to the unequal development of the tissues. The blackish-brown spots which mark the outer surface of the epicarp are made up of tannin-containing cells which appear to be under the influence of a local
stimulus of some kind, the area affected being 0.2 or 0.3 Mm. in diameter. The epidermal cells are more or less polygonal, the cuticle being from 2 to 5 microns thick (Fig. B, e). Beneath the epidermis are two to three rows of tabular cells, usually containing a reddish-brown or tannin-containing sap (Fig. B, c); beneath these subepidermal cells is a continuous ring or zone (Fig. B, s) made up of three or four layers of stone cells, the walls of which are strongly lignified, lamellated, and finely porous. The cells vary from tabular to irregular, and may or may not contain a reddish-brown tannin-like substance, the tannin being in the cells of the specialized areas already described.

Beneath this zone of stone cells occur the tissues of the sarcocarp proper (Fig. B, p). This portion consists of parenchyma and fibro-vascular tissue. The cells of the parenchyma contain small starch grains and occasionally rosette aggregates of calcium oxalate which vary in diameter from 25 to 40 microns, and sometimes may be found in large numbers in the parenchyma cells adjoining the fibro-vascular bundles.

The parenchyma cells of the sarcocarp of the young fruits have very thin walls, but in the older fruits the walls of very many of the cells become lignified and have large oblique pores. The tracheae are in radial rows usually two cells wide separated by medullary rays one cell wide. They are spiral.

At both the apical and basal portions of the fruit occur curved, spear-shaped, unicellular, non-glandular hairs (Fig. D) resembling those found on the pericarp of the cereal grains, but distinguished from the latter by the fact that they are frequently united to form stellate groups resembling those of kamala and those occurring on the leaves of Hamamelis. The contents may be colorless or consist of a brown reddish-brown tannin-like substance. There are also present, usually at the base of the fruit, and also on the stems, when these are present, long-stalked glandular hairs (Fig. E) similar to those covering the fruit of Juglans cinerea (Butternut.) While the stalk is long and multicellular in the hairs of both species, the glandular head in the hairs of Juglans regia appears for the most part to consist of one or two cells, whereas in Juglans cinerea it is usually multicellular, resembling the glandular heads of the hairs of the Labiatae.

In the parenchyma cells of the basal portion of the hull there are a large number of rosette aggregates or spherites of crystals resembling crystals of calcium oxalate (Fig. F). These aggregates are more or less hollow, frequently attached to the cell-wall, sometimes more or less enclosed by the cell-wall, and thus resemble the membrane crystals of Rosanoff (See Kraemer, Botany and Pharmacognosy). These aggregates differ from those found in the stem, which are the typical calcium rosette aggregates of calcium oxalate, and are deserving of special study.

Characteristics of the Powder.—The color is dark brown or blackish-brown, the odor faint, and the taste distinctly acid and slightly bitter.
Pericarp of fruit of *Juglans regia*.

A, stomata, of epicarp.

B, cross-section of pericarp, showing epidermis (e), cells with reddish-brown contents (c), sclerotic cells (s), parenchyma (p) containing protoplasm and starch grains.

C, mestome strand of the sarcocarp showing vessels (v), libriform (l), leptome (s), parenchyma containing protoplasm and starch (p).

D, non-glandular hairs from the apical and basal portions of fruit.

E, glandular hairs from base of fruit similar to those found in large numbers on the surface of the butternut (*Juglans cinerea*).

F, rosette-aggregates resembling the membrane crystals of Rosanoff.

G, sclerotic cells found in the powder.

H, fragment of non-glandular hair.

K, starch grains from 2 to 10 μ in diameter.

L, tracheae with annular markings.

M, calcium oxalate crystals.
The most characteristic elements of the powder are the stone cells (Fig. G.), some of which contain only air, thus resembling those of the olive pit, and some of which have a reddish-brown content; there occur besides fragments of the stalks of the glandular hairs (Fig. D), fragments of the non-glandular hairs (Figs. D and H), small starch grains, (Fig. K) the two types of rosette aggregates of calcium oxalate crystals (Figs. F. and M.), and large, thin-walled, somewhat shrunken parenchyma cells, many of which contain either small starch grains or reddish-brown masses, or cells with rather thick walls having large simple pores and being more or less lignified, approaching stone cells. The latter sometimes contain the Rosanoff crystal aggregates already mentioned.

When the hulls of *Juglans regia* are treated with water the solution soon shows a reddish-brown color which becomes much deeper on the addition of aqueous solutions of the alkalies. The aqueous extract of black pepper hulls, and black walnut shells (endocarp) have a color similar to that of the hulls of *Juglans regia* and behave similarly towards solutions of the alkalies. The aqueous extract of pecan shells (endocarp) is of bright-red or cherry red color, but becomes on the addition of alkalies of a dark reddish-brown color similar to that of the extract of the hulls of *Juglans regia*. Cloves give a reddish-yellow aqueous extract which becomes deep red on the addition of solutions of the alkalies. The aqueous extracts of the following are either nearly colorless or range from a pale yellow to a pale yellowish-red, or pale olive-green; and are not turned a dark reddish-brown on the addition of alkalies: Black pepper, white pepper, Ceylon cinnamon, Cassia cinnamon, Saigon cinnamon, pimenta, ginger, English walnut shells (endocarp), olive endocarp (olive pits), peanut shells, Brazil nut shells (seed coat), and butternut shells (endocarp).

**The Chairman:** The paper is now before you for discussion, if desired.

**Mr. Clark:** I would like to ask Dr. Kraemer if he has seen this adulteration in any particular substance, more than in others?

**Mr. Kraemer:** The substances in which I may have met this adulterant were powders that were supplied to us, and I did not consider it at the time of sufficient importance to indicate that something else was added, and it was not until my studies upon *Juglans* that I was inclined to the opinion that the stellate hairs possibly did not come there by accident. For instance, in a laboratory such as we have, it is possible to conceive that the stellate hairs of Kamala might have accidentally gotten upon the slide or in the reagent. When one meets something of this kind, which is manifestly out of the way, and not likely to be used as an adulterant, one would not suppose that Kamala had been used, I simply mention this because I have observed these branching or stellate hairs on a number of occasions. I can not for the moment recall just what powdered drugs were examined at the time.

**The Chairman:** If there is no further discussion, we will take up the next paper.

**Mr. Kraemer** here read his paper on “The Anatomy of Phlox Carolina.”

BY HENRY KRAEMER.

For some time I have felt the importance of making studies of the structure of the underground portions of American plants, as there are so many vegetable fragments of unknown origin in many cases which are found admixed with the more common drugs, and which have a superficial resemblance to them. Thus, unless careful garbling is practised, these foreign plant parts may not only be found as an admixture, but as an entire substitute for the genuine drug.

My interest in Phlox carolina dates back some twelve years when, at my request, Mr. C. D. Beadle, of the Biltmore Herbarium, sent me a number of plants which he collected in the mountains of North Carolina. While I did not make an extended study of the material at the time, I examined it sufficiently to lead to the conclusion* that the material which Greenish described in his paper did not answer to the description of Phlox carolina. My main object at that time was to determine the origin of a substitute for Spigelia, in which one of my students at Northwestern University discovered by accident the presence of calcium carbonate. This substitute was shown subsequently and independently by Stockberger † and Holm‡ to be the rhizome of Ruellia ciliosa.

In connection with their studies on Spigelia marilandica and Ruella ciliosa, these authors have also described the structure of Phlox ovata (Phlox carolina). While the papers of Stockberger and Holm are excellent contributions to the subject, there are still some features which should be brought out more distinctly, especially from the practical pharmacognostic point of view. Stockberger considers that the rhizome and roots of Phlox ovata "rarely or never occur as a substitute for Spigelia," and I agree with him in a measure, but its occurrence is still reported and, besides, workers do not seem to be clear in regard to the characters of the drug. I do not, however, agree with the statement made by Stockberger that "the root so generally described and studied as Phlox must be referred to Ruellia," which latter drug I hope to take up later.

In order that errors may be eliminated from the literature, it should be pointed out that in the English translation of Solereder's "Systematic Anatomy of the Dicotyledons," which appeared as recently as 1908, the translators continue the mistake in the original German edition of accepting as true the description given by Greenish § of what he had reason to

suppose was *Phlox carolina*, but which it has since been seen was not an authentic specimen. It should also be pointed out for the benefit of practical workers that the material studied by Professor Greenish was drug material, some of which was supplied by Professor Maisch, but neither of them is open to criticism, both of them having accepted as probably genuine what was supplied them, as was then more customary. Indeed, Professor Greenish did a very excellent piece of work, and nothing would have been left to be desired if he had known the name of the plant from which the material with which he worked was derived and had named his paper accordingly, that is, by substituting the name *Ruellia ciliosa* for *Phlox carolina*. Later experience also shows that it is extremely hazardous to base a study of a vegetable drug on the commercial material alone, and that no studies of this kind can be considered entirely reliable or authoritative which are not based upon material collected from or compared with that derived from plants which have been identified.

The species belonging to the genus *Phlox* are found chiefly in North America, where they number about thirty. The plants are mostly herbaceous perennials, a number of the species being extensively cultivated for ornamental purposes. The stems are either decumbent or ascending, or in some cases they are slightly decumbent near the base and then ascending, as in *Phlox ovata*. *Phlox ovata* is found in open mountainous woods from Alabama to Pennsylvania, and there are some colored plates representing this plant in the Botanical Magazine (t. 528 and 1344). According to Gray, in his "Flora of North America," *Phlox carolina* is merely a taller form of *Phlox ovata*, but having narrower, more tapering leaves and pointed calyx teeth, approaching *Phlox glaberrima*. According to botanists to-day, the form with ovate or ovate-lanceolate leaves is regarded as the typical species, and the name *Phlox carolina* has been superseded by *Phlox ovata*.

*Phlox ovata* generally attains a height of from 3 to 6 decimeters. The stems are cylindrical, smooth, and the diameter is from 2½ to 3½ Mm. Thus, they are seen to be slender stems, and in order to maintain their perpendicular position would need to be quite woody, especially in the lower portion, which they are. The so-called rhizome, which is merely an extension of the over-ground stem, is usually vertical, comprising from two to four nodes, and usually 1 to 2 Cm. long. From the nodes arise from two to four comparatively thick roots, which are sometimes nearly 2 Mm. in diameter in the fresh state, from 1 to 2 decimeters long, unbranched, and produce a large number of fine rootlets, especially near the free ends (Fig. A). The commonly vertical character of the rhizome of *Phlox ovata* is one of the features which distinguishes it from the rhizomes of both Spigelia and *Ruellia*, although it should be stated that occasionally decumbent stems are found which produce roots at the nodes. In neither case is that part of the stem producing roots a true rhizome.
Phlox ovata L. (Phlox carolina L.): A, lower portion of plant showing long roots, numerous rootlets at the end; B, parenchyma from cortex of rhizome showing two sclerotic cells (s); C, cross-section of portion of rhizome showing parenchyma of cortex (p) which contains protoplasm and starch grains, endodermis (e), leptome (s), trachee (v), libriform (t), wood parenchyma (w), parenchyma of pith containing starch grains and protoplasm (Pa); D, isolated sclerotic cells from cortex; E, vessels with annular and spiral thickenings; F, libriform cells; G, glandular hair from the leaf.
The rhizome, or underground part of the stem, is characterized by a strong development of woody tissue, which in transverse section occupies about one-half of the radius. The bark is about 0.5 Mm. in diameter, the xylem and phloem together are about 0.9 Mm. in diameter, and the radius of the pith is 0.3 Mm.

**Histological Characters of Rhizome.**—The epidermis in transverse section is made up of rounded tabular cells and is surrounded by a cuticle which is more or less lignified and 8 to 10 microns in thickness. Beneath the epidermis are two to four rows of collenchymatous cells, the remainder of the cortex being made up of about twelve rows of parenchyma cells, the walls of which are about 5 microns thick, the cells themselves being from 40 to 80 microns in diameter. All of the cells of the cortex are rich in protoplasmic contents, and sometimes contain a considerable number of small starch grains, 1 to 3 microns in diameter. Beneath the cells of the cortex there is usually a well-defined ring of endodermal cells, which may be more or less lignified, and which may also contain a few small starch grains. Beneath the endodermis is a layer of pericambial cells, which show one or two tangential divisions. Next beneath is the sieve, which is made up either of thin-walled, somewhat tabular cells, or of oval, very thick-walled cells. The sieve cells are rich in protoplasmic contents, and frequently contain a number of starch grains. The xylem portion of the fibrovascular bundles (Fig. C) is made up of at least two, and frequently three areas—an outer layer composed of compact, strongly lignified cells, which are present in more lignified stems but not here illustrated; a middle layer, as in Fig. C, in which there are radial rows of parenchyma cells separating the thick-walled, lignified cells; and a continuous zone of lignified cells, as in Fig. C. The tracheae are marked with bordered pores, and those near the centre of the rhizome have annular and spiral markings, the number of tracheae thus marked being rather striking and characteristic. Most of the lignified cells of the xylem are in the nature of tracheids, which are narrower and longer than those in Spigelia, being usually not more than 20 microns in diameter and about 500 microns long (Fig. F). The parenchyma cells in the outer layers of the wood not infrequently show the presence of a number of small starch grains similar to those already described. Underlying the xylem tissue somewhat tabular cells, resembling those of the sieve, sometimes occur, but for the most part all of the cells beneath the xylem, constituting the pith, are made up of somewhat thick-walled parenchyma cells resembling those of the cortex. The walls of these cells are non-lignified, and are wanting in simple pores. The cells are rich in protoplasmic contents, and may contain a large number of starch grains.

The most characteristic features of the rhizome *Phlox ovata* may be enumerated as follows: (1) The upright or vertical position of the rhizome; (2) the few rather long and comparatively thick roots extending from the
nodes; (3) the comparatively thick xylem; (4) the absence of an internal phloem, the fibrovascular bundles being of the collateral type, and (5) the presence of starch in at least the rhizomes of the fruiting plants. The fact that neither Stockberger nor Holm found starch in this rhizome is probably due to their having worked with material in which it was present in rather small quantities, the amount varying unquestionably with the season of the year. I especially mention this point, in view of the fact that Stockberger places Phlox in a group in which starch is wanting, and calls attention to its supposed absence as a differentiating character.

The tendency of this plant to produce mechanical cells is further shown by the fact that some of the cells of the pith as well as of the cortex are thick-walled, strongly lignified, the walls being marked by rather fine simple pores (Figs. B, D). These cells as they occur in the pith are either cubical, or elongated, and with square ends, while those in the cortex are narrow, with pointed or oblique ends, and from 100 to 500 microns in length. Somewhat similar stone cells are found in the stem of *Phlox pilosa* L. If the material containing these cells should be relatively abundant in a mixture, their presence would give another character for distinguishing the rhizome of Phlox from that of Spigelia. The stone cells in Ruellia are different in shape, and in addition are associated with cells containing calcium carbonate. The presence of these special, thick-walled lignified cells in the rhizome of Phlox may, however, be of infrequent occurrence, like the bast fibres in belladonna, which I have only occasionally seen, but which have been described by Schrenk, and therefore may not be of assistance in the identification of the drug. It might be mentioned in this connection, however, that groups of bast fibres have been found in *Phlox aristata* Michx., and a ring of bast fibers in the stem of *Phlox longifolia* Nutt., *P. Douglassi* Hook., and *P. acuminata* Pursh.

**Histological Characters of Root.**—A transverse section of the root shows (1) ordinary epidermal cells with root-hairs; (2) a hypodermis made up of radially elongated, more or less pentagonal cells; (3) a cortex, consisting of 12 to 20 rows of ellipsoidal rather thin-walled parenchymatous cells, which are rich in protoplasm and may contain small starch grains; (4) a peripheral layer of the central cylinder; (5) endodermis; (6) internal layer of cortex, and (7) within this there is in the very young roots a triarch to pentarch radial fibrovascular bundle, which later becomes collateral and closely resembles in structure that of the rhizome.

While the stem is free from hairs the leaves have rather striking glandular hairs (Fig. G), which are found on the principal veins near the base of the leaf. The histological characters of the leaf have been very well given by Holm, and it therefore does not seem necessary to consider them here.

I may say in conclusion that I am engaged in the study of the structure of the underground parts of other species of Phlox, as possibly the
rhizomes, and roots of other species may occur as admixtures in drugs, and besides the genus is of great interest botanically.

**The Chairman:** The paper is before you for discussion.

**Mr. True:** I have listened to Dr. Kraemer with great interest, because about fifteen years ago the condition of the material known as spigelia, on the market, came to my attention, and at that time in overhauling samples that came from various commercial sources, I was led to the conclusion that things were not right with this phlox, and looked into the question of the adulteration of phlox in spigelia. I could find no evidence of phlox being present. Somewhat by accident, it was about 1893, I believe, I ran across evidence sufficient to convince me that the adulterant present was not phlox, as was supposed, and I felt justified in assigning this thing to the genus *Ruellia*. A brief note on this subject was published at the time. Sometime later we wished to make a purchase of spigelia for our drug garden. This was most ten years ago. We bought the roots and put them in, and to my dismay they came out very light, but gave us the material that was necessary for my own use; we were able to identify it botanically, and have grown it in our drug garden at Arlington. In our display upstairs you will find a number of the plants that we have grown in our drug garden, and which at Dr. Rusby's request we have sent down here. The question of phlox, as Dr. Kraemer has discussed it here, is extremely interesting, as I have said. I am interested to know that he has found starch. I might further say, to add to the oddity of the situation, that Dr. Stockberger had this plant growing, and we had it under observation year after year and did not find it. I may say, however, that this material was grown, and came to us from the north. It was originally southern material and taken to the Harvard Botanic Garden, and acclimatized there, and brought from there south—so this material has had a season in the north. Whether that would change its habits in any way, I don't know. The fact that Dr. Kraemer finds starch, seems to me to be rather as was expected, and I have been extremely interested to hear all he said about it. In view of the fact that *Phlox Carolina* has not had as much attention given to it heretofore as its importance in the laboratory would seem to require, I think Dr. Kraemer's paper is a very happy contribution to this already voluminous literature.

**Mr. Kraemer:** I have not brought out in this paper, that the whole genus of Phlox is known to have reserve starch. It is referred to by Solereder, in his "Systematic Anatomy of the Dicotyledons" so that it is not very remarkable that I should have found it present. My material is of fruiting plants collected in the vicinity of Asheville, North Carolina, and has considerable starch in it. The important point I have tried to bring out is not so much the presence of starch, but the undue emphasis that has been laid upon the absence of it as a characteristic *Phlox* carolina.

**The Acting Chairman:** It is rather unfortunate that our Chairman is not with us this afternoon, as he is familiar with the program, whereas your acting chairman is entirely unfamiliar with it.

**Mr. Dohme:** May I interject a matter which I think of interest, and which can be disposed of by the Section? I have in my hand a copy of the principles to be handed to the Committee of Revision, of the U. S. Pharmacopoeial Convention and I have been asked to present it to this Section and request the Section to take such action on them as it seems fit, before they are brought up in the general convention to-morrow. You will recall that the Committee on the U. S. P. made these recommendations and they were ordered to be printed and distributed among the members, so that they would be in position to vote upon them tomorrow, in the general convention. Mr. Beringer asked
me to bring them down here, and he will be here a little later in order to discuss them. I will put them in your hands, and I think it would be well to distribute them among the members here.

**ACTING CHAIRMAN**: As the Chair remembers the situation, action was to be taken on these recommendations at the close of this Section. Inasmuch as this is the closing session of this Section I presume action will have to be taken on them at this session. If agreeable, we will continue our program, and probably by the time we conclude it our Chairman will be back, and also Mr. Beringer will be present, and we can then take the matter up.

The next paper on the program is on "The Stability of Calcium Sulphide Tablets," by H. Engelhardt and M. R. Schmidt.

The paper was here presented by Mr. Dohme.

**CALCIAUM SULPHIDE PILLS AND TABLETS.**

**BY M. R. SCHMIDT AND H. ENGELHARDT.**

Having received a complaint alleging deterioration of a lot of Tablet Triturates Calcium Sulphide during the course of a year, we thought it advisable to make a rather detailed study of the question, and accordingly examined 70 samples of calcium sulphide preparations, including sugar-coated and chocolate-coated tablets, tablet triturates, as well as gelatin-coated pills.

The following method was used: 20 Cc. of tenth-normal iodine solution were run into a glass-stoppered flask for every grain of calcium sulphide, tablets or pills added, usually amounting to 1 or 2 grains, and the mixture made strongly acid with hydrochloric acid. The flask was allowed to stand with frequent shaking until the calcium sulphide was decomposed. The excess of iodine was titrated back, and each Cc. of iodine solution consumed in oxidizing the hydrogen sulphide to sulphur represents .0036 Gm. of calcium sulphide. The weight of calcium sulphide indicated was then divided by .55, the content of absolute calcium sulphide required by U. S. P. and the quotient divided by the grainage of the tablet or pill under examination, expressed in grams. The figure thus obtained multiplied by 100 represents the actual percentage of the grainage on the label which was present in the tablets.

Our results show that in no case has noticeable deterioration taken place, and some of the preparations were as much as three years old. Averaging all the results, we found that about 105 per cent. of the grainage stated on the label is actually present. In order to determine whether superficial deterioration might have taken place, one dozen samples of triturates were selected, with grainages ranging from 1/4 to 2 grains. After weighing four of each lot, about 25 to 40 per cent. of each tablet was cut off from the outside, the remaining inside portion weighed, and the calcium sulphide determined in this remainder as before. The amount of
calcium sulphide found in the reduced tablet was equal to the amount calculated from the reduced weight, within the limits of experimental error.

In connection with these experiments we procured tablets of several different makes and different grainages in the open market, and we found that these tablets likewise came up satisfactorily to the required strength.

A representative sample of a lot of calcium sulphide was also assayed, and showed 58.50 per cent. Calcium Sulphide. This figure is 106.3 per cent. of the U. S. P. standard, and agrees very well with the excess grainage found in the preparations.

The Acting Chairman: Is there any discussion on this paper?

Mr. Dohme: As long as this matter is up for consideration by the Revision Committee, and the Committee on Pharmacopoeia, I think I can give some very interesting information, which would be of service to the committee. About four years ago the then superintendent of our establishment, made a series of experiments, I believe about seventy-five, of the triturates, selecting particularly those that were prone to change, such as the iodides of mercury, and some of the alkaloid triturates, and a general line covering most of those generally used. He examined them a month after they were made, and put them in an ordinary clean bottle and exposed them on the shelf in his laboratory, so that they would have about the same conditions surrounding them as in a retail drug store. He examined them at the end of a year and found that not one had lost any percentage at all in its active ingredients. He then examined them again at a subsequent period, which I think was about two years after he made his first experiment, and found that none of them had lost any of their active ingredients, to his great surprise; and in his paper he attributed it, as I have always attributed it, to the preservative qualities of sugar of milk; that the reducing qualities of sugar of milk are a sufficient protection.

Mr. Vanderkleeft: I am glad to see this question of the permanence of the tablet triturates brought out, owing to the fact that it has been stated on many occasions that tablets of certain kinds were unstable. I think that the study of this question will serve to emphasize the point that Dr. Dohme has brought out, that these preparations are quite stable; and also that variations in them are due not to subsequent deterioration, but to the fault of the manufacturer in the first place, and the idea that the tablet is deteriorating is rather due to the fact that it never was right. I think a study of the tablets on the market is a very valuable one to undertake and report upon.

Mr. C. E. Caspari: I have heard a little different experience from that of Dr. Dohme, especially with tablets of mercury; these were made with sugar of milk, and not exposed to the light at all; there was a marked reduction, and at the same time oxidation; they changed color very rapidly.

Mr. Dohme: Of course it is an essential thing that your sugar of milk should be absolutely pure. You have to reject some every now and then. Of course there is sugar of milk made that is really not fit for use as a medicinal agent, because it is evidently very carelessly and imperfectly made; and it is a very important matter in pharmaceutical preparations to get your sugar of milk of the very highest grade of purity, and free from the presence of organic substances which are apt to be present. My experience has been that if you get it from the right source, and demand the right kind of crystals, you have very little trouble with this substance. I might say that the fact that some triturates, made by some people, will not keep the way they should, is probably due to
the fact that they do not exercise the necessary care in the examination of their sugar of milk.

**The Chairman:** If there is no further discussion, we will pass on to the next paper—"The Composition of Strychnine Arsenate," by W. A. Puckner and L. E. Warren.

Mr. Puckner here presented the paper just mentioned, and also the one following on the program, by the same authors, "The Composition of Commercial Copper Citrate."

**THE COMPOSITION OF STRYCHNINE ARSENATE.**

**W. A. PUCKNER AND L. E. WARREN.**

The consideration of strychnine arsenate was taken up by the Council with the view of its inclusion with New and Nonofficial Remedies. As very little information could be obtained concerning the chemistry of this salt, and some of the statements found were contradictory, the Association laboratory deemed it advisable to examine the several brands of the product as now sold on the American market. Accordingly specimens of these were purchased and submitted to examination.

Strychnine arsenate was probably first prepared by Chiappero.* He obtained it in two forms. The "arseniate" was prepared by heating 3.34 parts of strychnine with 1.15 parts arsenic acid dissolved in 40 parts of water. This salt, according to Chiappero, contains 1 molecule of alkaloid, 1 of acid and 5 molecules of water. It is said to be soluble in 15 parts of water.

The "subarseniate" was prepared by heating 6.6 parts of strychnine in 1.15 parts arsenic acid dissolved in 40 parts of water. According to Chiappero this salt contains 2 molecules of alkaloid, to 1 of acid and 6 molecules of water, and requires 40 parts of water for solution.

The literature contains but very little information concerning the properties of strychnine arsenate and that little is very contradictory. For example, in Squibb's Materia Medica† the solubility (of the salt sold by that firm) is given as 1 in 70 of water. Merck's Index‡ gives the solubility as 1 in 14 of water, while, as previously noted, Chiappero's salts are said to be soluble in 15 and 40 parts of water respectively.

Specimens of strychnine arsenate were examined, which were sold under the labels of the following firms: E. R. Squibb & Sons; Merck & Co.; Mallinckrodt Chemical Works, and Powers, Weightman, Rosengarten Co.

Squibb's product was a coarse white powder which, under the microscope, was seen to be composed of colorless, transparent prisms. Merck's specimen was a white crystalline powder. Mallinckrodt Chemical Works specimen was a coarse, crystalline white powder with a faint yellowish

---

* Cann. Jahrber. f. Pharm., 152 (1861); also A.Ph.A., Proc. 17, 151 (1863).
† Squibb's Materia Medica, 232 (1906).
‡ Merk's Index, 426 (1907).
tinge. It was made up of colorless transparent prisms and opaque faintly yellowish white masses. The Powers, Weightman, Rosengarten Co. specimen was similar in appearance to the Squibb specimen.

**ANALYTICAL.**

_Solubility._—The solubility of strychnine arsenate in water at 25° C. was determined in 2 specimens. The determinations were made according to the method, and in the apparatus described by Pawlenski. (Ber., 23, 230, 1908). About 3 Gm. of the finely powdered salt and 10 c.c. of water were employed in each of the determinations, thus using a large excess of the salt over its solvent.

_Results._—P. W. R. Brand; 8.8926 Gm. of the saturated solution gave 0.4047 Gm. dried residue, equivalent to 0.42907 Gm. crystallized salt. 8.8926 Gm. solution contain 0.42907 Gm. salt and 8.49633 Gm. water. 0.42907 Gm. salt dissolved in 8.49633 Gm. water indicates a solubility of 19.80 at 25° C. for the crystallized salt. 8.9260 Gm. of the solution contain 0.4047 Gm. anhydrous salt and 8.5213 Gm. water, equivalent to solubility of 21.03 for the anhydrous substance at 25° C. 7.4861 Gm. of the aqueous solution saturated at 25° C. gave a dry residue of 0.3380 Gm., equivalent to 0.35834 Gm. crystallized salt. 7.4861 Gm. of the solution contain 0.35834 Gm. crystallized salt and 7.12776 Gm. water, equivalent to a solubility of 19.89 in water at 25° C. 7.4861 Gm. of the solution contain 0.3380 Gm. dry salt and 7.1481 Gm. water, corresponding to a solubility of 21.15 for the dry salt at 25° C. Average: 1 part crystallized strychnine arsenate (P. W. R. brand) requires 19.85 parts of water for solution at 25° C.; 1 part anhydrous strychnine arsenate requires 21.09 parts of water for solution at 25° C. M. C. W. brand; 8.0954 Gm. of the aqueous solution at 25° C. gave 0.3759 Gm. dried residue, equivalent to 0.38016 Gm. crystallized substance. 8.0954 Gm. of the solution contain 0.38016 Gm. salt and 7.71524 Gm. water, equivalent to a solubility of 20.30 at 25° C. 8.0959 Gm. solution contain 0.3759 Gm. anhydrous salt and 7.7200 Gm. water, equivalent to a solubility of 20.54 at 25° C. 6.3436 Gm. of the aqueous solution saturated at 25° C. gave 0.2885 Gm. dry residue, equivalent to 0.29177 Gm. crystallized substance. 6.3436 Gm. of the solution contain 0.29177 Gm. strychnine arsenate and 6.05183 Gm. water, corresponding to a solubility of 20.74 at 25° C. for the crystalline substance. 6.3436 Gm. of the solution contain 0.2885 Gm. anhydrous strychnine arsenate and 6.0551 Gm. water, corresponding to a solubility at 25° C. of 20.98. Average: 1 part of crystallized strychnine arsenate (M. C. W. brand) requires 20.48 parts of water for solution at 25° C; 1 part of the anhydrous salt requires 20.76 parts of water for solution at 25° C. As was to be expected, the solubility of the specimen containing the most water of hydration required less water for its solution than the other.*

*As this article is completed, Schaefer's paper, "Solubility of Alkaloids of Cinchona
**THE COMPOSITION OF STRYCHNINE ARSENATE.**

**Water.**—A weighed quantity of the salt was dried at 100° C., and the loss calculated as water. In the different specimens examined, water was found in amounts varying from 1.1 per cent. to 5.7 per cent.

**Results.**—Squibb brand; 0.5023 Gm. lost 0.0083 Gm., equivalent to 1.65 per cent.; 0.5029 Gm. lost 0.0084 Gm., equivalent to 1.67 per cent.; average, 1.66 per cent. water. Merck brand; 1.0099 Gm. lost 0.0236 Gm., equivalent to 2.34 per cent.; 1.0005 Gm. lost 0.0215 Gm., equivalent to 2.15 per cent.; average, 2.24 per cent. water. M. C. W. brand; 1.0 Gm. lost 0.0112 Gm., equivalent to 1.12 per cent.; 1.0029 Gm. lost 0.0113 Gm., equivalent to 1.12 per cent.; average, 1.12 per cent. water. P. W. R. brand; 1.0065 Gm. lost 0.0571 Gm., equivalent to 5.67 per cent.; 1.0016 Gm. lost 0.0577 Gm., equivalent to 5.69 per cent.; average 5.68 per cent. water.

**Alkaloid.**—One Gm. of the material was dissolved in about 50 Cc. water in a separator, a slight excess of ammonia water added, and the mixture extracted successive with several small portions of chloroform until extraction was complete. The chloroformic solutions were combined, placed in a separator and washed with 25 Cc. of water. The chloroform was drawn off, evaporated, the residue dried at 100° C. and weighed. In the several specimens examined alkaloid was found in amounts varying from 66.3 per cent. to 69.7 per cent.

**Results.**—Squibb brand; 1.0002 Gm. gave 69.89 Gm. alkaloid, equivalent to 69.88 per cent.; 1.0006 Gm. gave 0.6965 Gm. alkaloid, equivalent to 69.61 per cent.; average, 69.74 per cent. alkaloid. Merck brand; 1.0099 Gm. gave 0.6973 Gm. alkaloid, equivalent to 69.05 per cent.; 1.0005 Gm. gave 0.6902 Gm. alkaloid, equivalent to 68.98 per cent.; average, 69.02 per cent. alkaloid. M. C. W. brand; 1.0 Gm. gave 0.6872 Gm. alkaloid, equivalent to 68.72 per cent.; 1.0029 Gm. gave 0.6879 Gm. alkaloid, equivalent to 68.59 per cent. alkaloid; average, 68.66 per cent. alkaloid. P. W. R. brand; 1.0065 Gm. gave 0.6672 Gm. alkaloid, equivalent to 66.29 per cent.; 1.0016 Gm. gave 0.6646 Gm. alkaloid, equivalent to 66.35 per cent.; average, 66.32 per cent. alkaloid.

**Arsenic Acid.**—The aqueous solution remaining in the separator after removal of the alkaloid by chloroform, together with the aqueous washings from the chloroformic solution of the alkaloid, was evaporated to 25 Cc., magnesia mixture added, and the determination completed according to the method given in Olsen’s Quantitative Chemical Analysis, p. 86 (1904). The results were calculated to arsenic acid (H₃AsO₄).

\[ \text{Mg}_2\text{As}_2\text{O}_7 \times 0.91411 = \text{H}_3\text{AsO}_4. \]

Bark and Their Salts in Water at a Temperature of 25° C.” (Am. Jour. Pharm., 82, 175, 1910) has come to our notice. Experiments to determine the bearing of this on the above solubility determinations are under way.
The quantities of arsenic acid found by this method varied from 27.2 per cent. to 28.9 per cent.

Results.—Squibb brand: 1.0002 Gm. gave 0.3111 Gm. magnesium pyro-arsenate, equivalent to 28.43 per cent. arsenic acid; 1.0006 Gm. gave 0.3103 Gm. magnesium pyro-arsenate, equivalent to 28.35 per cent. arsenic acid; average, 28.39 per cent. arsenic acid. Merck brand: 1.0099 Gm. gave 0.3116 Gm. magnesium pyro-arsenate, equivalent to 28.20 per cent. arsenic acid; 1.0005 Gm. gave 0.3091 Gm. magnesium pyro-arsenate, equivalent to 28.24 per cent. arsenic acid; average, 28.22 per cent. arsenic acid. M. C. W. brand: 1.0000 Gm. gave 0.3184 Gm. magnesium pyro-arsenate, equivalent to 29.11 per cent. arsenic acid; 1.0029 Gm. gave 0.3152 Gm. magnesium pyro-arsenate, equivalent to 28.73 per cent. arsenic acid; average, 28.92 per cent. arsenic acid. P. W. R. brand: 1.0065 Gm. gave 0.2997 Gm. magnesium pyro-arsenate, equivalent to 27.22 per cent. arsenic acid; 1.0016 Gm. gave 0.2974 Gm. magnesium pyro-arsenate, equivalent to 27.14 per cent. arsenic acid; average, 27.18 per cent. arsenic acid.

The arsenic was also determined by the sulphur dioxide reduction method (Rep. Chem. Lab. A. M. A. Vol. 1, p. 13). It consists in reducing the arsenic acid with sulphur dioxide in a pressure bottle, and subsequently titrating the arsenous acid with iodine in presence of sodium bicarbonate.

\[
1 \text{Cc. } \frac{\text{x}}{10} \text{ I} = 0.007046 \text{ Gm. } \text{H}_3\text{AsO}_4.
\]

By this method arsenic acid (\(\text{H}_3\text{AsO}_4\)) was found in the several specimens examined in quantities ranging from 26.6 per cent. to 27.8 per cent.

Results.—Squibb brand: 0.5023 Gm. required 19.73 Gm. tenth-normal iodine, equivalent to 27.67 per cent. arsenic acid; 0.5029 Gm. required 19.82 Gm. tenth-normal iodine, equivalent to 27.77 per cent. arsenic acid; average, 27.72 per cent. arsenic acid. Merck brand: 0.5041 Gm. of the material required 19.72 Gm. tenth-normal iodine, equivalent to 27.57 per cent. arsenic acid; 0.5010 Gm. required 19.62 Gm. tenth-normal iodine, equivalent to 27.40 per cent. arsenic acid; average, 27.48 per cent. arsenic acid. M. C. W. brand: 0.5022 Gm. of the material required 19.775 Gm. tenth-normal iodine, equivalent to 27.75 per cent. arsenic acid; 0.5027 Gm. required 19.93 Gm. tenth-normal iodine, equivalent to 27.93 per cent. arsenic acid; average, 27.84 per cent. arsenic acid. P. W. R. brand: 0.5045 Gm. of the material required 21.66 Gm. tenth-normal iodine, equivalent to 26.57 per cent. arsenic acid; 0.5012 Gm. required 18.90 Gm. tenth-normal iodine, equivalent to 26.59 per cent. arsenic acid; average, 26.58 per cent. arsenic acid.

The analytical results obtained in the examination of the several brands are briefly shown in the appended table:
THE COMPOSITION OF STRYCHNINE ARSENATE.

* Since the determinations of the arsenic acid by the two methods did not agree very closely, the methods were compared by working upon a solution of known arsenic content. A solution of arsenic acid was prepared by dissolving 3.4850 Gm. pure arsenic trioxide (Merck's reagent) in 50 Cc. of concentrated hydrochloric acid, adding sufficient concentrated nitric acid to oxidize the arsenous compound to the arsenic condition, boiling the solution in a reflux apparatus until free from chlorine vapors, and diluting the solution to 1 liter with distilled water. Qualitative tests indicated that the solution was free from arsenous compounds. Each Cc. of this solution contains 0.0050 Gm. arsenic acid (H₃AsO₄). The results obtained are given in the following tables:

In Merck’s Index (1907) the formula for strychnine arsenate is given as \( \text{C}_{21}\text{H}_{22}\text{N}_{2}\text{O}_{5}\text{.H}_{3}\text{AsO}_{4} + \frac{1}{2}\text{H}_{2}\text{O} \). This corresponds to:

- Strychnine .................................................. 68.88 per cent.
- Arsenic Acid ............................................... 29.26 per cent.
- Water ......................................................... 1.86 per cent.

The Squibb, the Merck and the Mallinckrodt specimens conform in a general way to the formula, \( \text{C}_{21}\text{H}_{22}\text{N}_{2}\text{O}_{5}\text{.H}_{3}\text{AsO}_{4} + \frac{1}{2}\text{H}_{2}\text{O} \), while the Powers-Weightman-Rosengarten specimen conforms more nearly to the formula \( \text{C}_{21}\text{H}_{22}\text{N}_{2}\text{O}_{5}\text{.H}_{3}\text{AsO}_{4} - \frac{1}{2}\text{H}_{2}\text{O} \). A glance at the subjoined table of analytical results and calculations will suffice to show the comparisons:

Since strychnine arsenate as found on the American market varies somewhat in composition, the following provisional description of the product has been prepared:

**Strychnine Arsenate. Strychninae Arsenas.**—Strychnine arsenate \( \left( \text{C}_{21}\text{H}_{22}\text{N}_{2}\text{O}_{5}\text{.H}_{3}\text{AsO}_{4} + \frac{1}{2}\text{H}_{2}\text{O} \right) \) is the binary strychnine salt of arsenic acid. Strychnine arsenate should contain alkaloid corresponding to between 68 and 70 per cent. of anhydrous strychnine.

Strychnine arsenate occurs as a white, crystalline powder: or in small, colorless or faintly yellowish, transparent, or slightly opaque prisms; or in white, acicular crystals; odorless and having an extremely bitter taste. *Strychnine arsenate should be tasted with extreme caution.*

Slowly soluble in about 20 parts of water at 25° C., more readily soluble in hot water; slightly soluble in alcohol; insoluble in chloroform or ether. Its aqueous solutions are colorless and are precipitated by alkaline hydroxides and by alkaline carbonates. It is incompatible with alkalies and their carbonates, with tannic acid and other precipitants of the alkaloids.
Strychnine arsenate undergoes hydrolysis in aqueous solution so that if such a solution be shaken with chloroform an appreciable quantity of free alkaloid may be removed.

When heated to 100° C. (212° F.) the salt loses its water of crystallization. At about 210° C. (410° F.) it begins to decompose without melting. At still higher temperature the salt chars, ignites and is finally dissipated.

When dried at 100° C. (212° F.) strychnine arsenate should not lose more than 2 per cent. of its weight. In absence of an undue amount of water.

Sulphuric acid should produce no color with strychnine arsenate, but on adding a fragment of potassium dichromate, a blue color should be produced, changing to deep violet, then to purplish-red, cherry-red, and finally to orange or yellow. Sulphuric acid containing 1 per cent. of ammonium vanadate produces a deep violet-blue color, changing to deep purple, and finally to cherry-red. Sulphuric acid containing a trace of potassium iodate produces a violet color, changing to reddish-purple.

If 0.1 Gm. of the salt be dissolved in a few drops of nitric acid, the solution evaporated to dryness, and a few drops of ammonia water added to the yellow residue, an orange-red color will be produced, which will turn momentarily reddish-purple, and finally brown, on the addition of a small amount of alcoholic potassium hydroxide test solution.

If a little strychnine arsenate be treated with a few drops of nitric acid, on a white porcelain surface, not more than a faint yellow color should be produced. (limit of brucine).

If an aqueous solution of strychnine arsenate (1:50) be made slightly alkaline with ammonia water, and the alkaloid subsequently removed by shaking with chloroform, portions of the solution after being boiled to expel the dissolved chloroform and excess ammonia and acidified with nitric acid, should not give more than a very slight test for sulphates. Another portion of this solution should give upon the addition of magnesia mixture a white precipitate of magnesium-ammonium arsenate which soon becomes crystalline. Another portion of this solution, when treated with a few Cc. of diluted sulphuric acid and a few drops of iodine test solution, should not discharge the color due to iodine (absence of arsenite).

If an aqueous solution of strychnine arsenate (1:50) be acidified with diluted nitric acid and a few drops of silver nitrate test solution be added, not more than a slight opalescence should be given (limit of chloride).

Chemical Laboratory of the American Medical Association.

THE COMPOSITION OF COMMERCIAL COPPER CITRATE.

W. A. PUCKNER AND L. E. WARREN.

While definite standards of quality are provided for substances official in the U. S. Pharmacopeia, no definite standards are, as a rule, set for non-official substances. It is, therefore, particularly important that the non-
official products as found on the market be subjected to control. With this idea in view the Chemical Laboratory of the American Medical Association devotes some time to the examination of unofficial substances as they occur on the American market.

The employment of different processes by different makers for the manufacture of the same article naturally results in some variations in the appearance and quality of the finished product. These variations, however, should not exceed a reasonable limit either for standards of strength or for impurities which may unavoidably remain in the finished product.

Copper citrate, a substance occasionally used in medicine, may be taken as an example of the conditions which result from the lack of authoritative standards to guide the manufacturer in the preparation of his wares. Copper citrate, as employed in medicine, is a salt of citric acid in which the copper is present in the cupric state. Several citrates of copper have been described, but considerable confusion exists in the literature concerning the composition of the medicinal salt.

The chemical literature of copper citrate dates from 1833, when the salt appears first to have been prepared by Liebig* and his pupils while working out the formula for citric acid. They obtained the salt by heating a solution of copper acetate with a solution of citric acid. Gay-Lussac made an analysis of the salt and ascribed the following formula to it:

\[ \text{4CuOC}_{12}\text{H}_{10}\text{O}_{114}\text{Aq.} \text{ (Old atomic weights).} \]

In 1843 Heldt studied a large number of the salts of citric acid. He prepared copper citrate † by heating a solution of copper acetate with citric acid. He also obtained the salt by heating copper carbonate with a solution of citric acid. From the results of an analysis of the salt which had been dried over sulphuric acid for 24 hours, he calculates the formula, \( \text{4CuOC}_{12}\text{H}_{10}\text{O}_{113}\text{H}_{2}\text{O} \) (old atomic weights). Heldt states that at 100 degrees the salt loses \( \frac{2}{3} \) of its water of hydration, or 5.41 per cent., and at 150 degrees the whole of the water is lost, or 7.53 per cent. At 170 degrees decomposition takes place.

Kämmerer ‡ obtained copper citrate by heating a solution of sodium citrate with copper sulphate in great dilution, and also by adding citric acid to a hot solution of copper sulphate and potassium acetate. The product obtained by each process was analyzed, and the two salts were found to be identical. Somewhat later Kämmerer § obtained another copper citrate by dissolving copper carbonate in citric acid, filtering and

† Annal. Chem. Pharm., 47, 193 (1843).
‡ Annal. Chem. Pharm., 148, 393 (1868).
§ Ibid., 170, 186 (1873).
precipitating the copper citrate by the addition of alcohol. The formula for this salt is said to be 

\[ \text{Cu}_2 \text{H}_2(\text{C}_6 \text{H}_4 \text{O}_7)_3 + 15 \text{H}_2 \text{O}. \]

The formula \( \text{Cu}_2 \text{C}_6 \text{H}_3 \text{O}_7 + 2\frac{1}{2} \text{H}_2 \text{O} = \frac{1}{2} \left[ \text{Cu}_2(\text{C}_6 \text{H}_4 \text{O}_7)_3 + 5 \text{H}_2 \text{O} \right] \) is given for copper citrate by Beilstein,* by Schmidt,† and is found in Merck’s Index.‡ Hager § gives the formula, \( \text{Cu}_2 \text{C}_6 \text{H}_3 \text{O}_7 + 2 \frac{1}{2} \text{H}_2 \text{O} \).

In the attempt to obtain more definite information concerning the composition of commercial copper citrate the examination of the market product was undertaken.

Four original packages of copper citrate bearing the labels of as many firms were purchased. These products varied somewhat in physical character and appearance. The specimen bearing the Merck label was a bright green powder, was noticeably gritty to the touch, and possessed a noticeable odor like acetic acid; Mallinckrodt’s specimen was a pale bluish-green, odorless powder, slightly gritty to the touch. The specimen sold under the label of Powers, Weightman, Rosengarten Co., was a pale green odorless powder. In general appearance it was very similar to the P. W. R. specimen.

**ANALYTICAL.**

All of the specimens responded to tests of identity for copper and citrate. With the exception of the Merck specimen, which by its odor indicated the presence of acetic acid, all of the specimens gave tests for sulphates.

**Water.**—This was determined by heating in an air bath at 100° C. until an approximately constant weight was obtained. When the temperature was gradually raised to 150° C. some further loss was noted, but constant weight could not be obtained. At 100° C. a loss of from 5.4 per cent. to 6.7 per cent. was found for the different specimens. At 150° C. the highest observed loss was 7.6 per cent.

**Results.**—Merck brand; 0.8171 Gm. lost 0.0555 Gm., equivalent to 6.79 per cent.; 0.9493 Gm. lost 0.0637 Gm., equivalent to 6.71 per cent.; average, 6.75 per cent. water. M. C. W. brand; 0.6534 Gm., lost 0.0360 Gm., equivalent to 5.51 per cent.; 0.7291 Gm. lost 0.0393 Gm.; equivalent to 5.35 per cent.; average, 5.43 per cent. water. P. W. R. brand; 0.5206 Gm. lost 0.0343 Gm., equivalent to 6.59 per cent.; 0.992 Gm. lost 0.0685 Gm., equivalent to 6.86 per cent.; average, 6.72 per cent. water. Squibb brand; 1.0024 Gm. lost 0.0676 Gm., equivalent to 6.74 per cent.; 1.0080 Gm. lost 0.0676 Gm., equivalent to 6.72 per cent.; average, 6.73 per cent. water.

**Copper.**—To 0.5 Gm. of the material 25 Cc. water and 10 Cc. normal

---

† Pharm. Chem., 2, 575 (1901).
‡ Merck’s Index, 154 (1907).
sulphuric acid were added. The mixture was agitated, heated almost to boiling and maintained at that temperature until solution took place, a little more of the normal acid being added if necessary. After the solution had cooled, 10 Cc. of potassium iodide test solution were added, the mixture allowed to stand for five minutes with occasional shaking, 200 Cc. water added, and the liberated iodine titrated with tenth-normal sodium thiosulphate.

1 Cc. $\frac{N}{10}$ Na$_2$S$_2$O$_3$ 0.000631 Gm. Cu.

The amounts of copper in the specimens examined varied from 34.1 per cent. to 35.2 per cent.

Results.—Merck brand; 0.4049 Gm. required 22.61 Cc. tenth-normal sodium thiosulphate, equivalent to 0.1427 Gm. copper, or 35.24 per cent.; 0.4019 Gm. required 22.42 Cc. tenth-normal thiosulphate, equivalent to 0.1414 Gm. copper, or 35.20 per cent.; average, 35.22 per cent. copper. M. C. W. brand; 0.4014 Gm. required 12.18 Cc. tenth-normal sodium thiosulphate, equivalent to 0.13994 Gm. copper, or 34.86 per cent.; 0.4007 Gm. required 22.18 Cc. tenth-normal sodium thiosulphate, equivalent to 0.13994 Gm. copper, or 34.92 per cent.; average, 34.89 per cent. copper. P. W. R. brand; 0.3062 Gm. required 16.57 Cc. tenth-normal sodium thiosulphate, equivalent to 0.10459 Gm. copper, or 34.15 per cent.; 0.5172 Gm. required 28.0 Cc. tenth-normal sodium thiosulphate, equivalent to 0.17665 Gm. copper, or 34.16 per cent.; average, 34.15 per cent. copper. Squibb brand; 0.3899 Gm. required 21.11 Cc. tenth-normal sodium thiosulphate, equivalent to 0.1352 Gm. copper, or 34.16 per cent.; 0.5585 Gm. required 30.15 Cc. tenth-normal thiosulphate, equivalent to 0.19024 Gm. copper, or 34.06 per cent.; average, 34.11 per cent. copper.

Sulphate.—A weighed quantity of the material was dissolved in diluted hydrochloric acid by the aid of heat, solution of barium chloride was added, and the barium sulphate collected and weighed in tared Gooch crucibles. The results were calculated to SO$_4$ and to crystallized copper sulphate (CuSO$_4$·5H$_2$O). In the specimens containing sulphate as an impurity, sulphate equivalent to crystallized copper sulphate was found in amounts varying from 1.7 per cent. to 6.4 per cent.

Results.—M. C. W. brand; 1.5135 Gm. gave 0.0246 Gm. barium sulphate, equivalent to 0.01012 Gm. SO$_4$, or 0.668 per cent.; 2.5340 Gm. gave 0.0409 Gm. barium sulphate, equivalent to 0.01683 Gm. SO$_4$, or 0.664 per cent.; average, 0.666 per cent. SO$_4$, equivalent to 1.73 per cent. crystallized copper sulphate (CuSO$_4$·5H$_2$O). P. W. R. brand; 2.0963 Gm. gave 0.1203 Gm. barium sulphate, equivalent to 0.0495 Gm. SO$_4$, or 2.36 per cent.; 2.0215 Gm. gave 0.1146 Gm. barium sulphate, equivalent to 0.047157 Gm. SO$_4$, or 2.33 per cent.; average, 2.35 per cent SO$_4$, equivalent to 6.10 per cent. crystallized copper sulphate (CuSO$_4$·5H$_2$O). Squibb brand: 1.2615 Gm. gave 0.0762 Gm. barium sulphate, equivalent
to 0.031356 Gm. SO₄, or 2.49 per cent.; 1.6755 Gm. gave 0.1007 Gm. barium sulphate, equivalent to 0.04143 Gm. SO₄, or 2.47 per cent.; average, 2.48 per cent. SO₄, equivalent to 0.44 per cent. crystallized copper sulphate (CuSO₄.5H₂O).

**Citric Acid.**—An attempt was made to determin citric acid by precipitation of the copper as sulphide, expulsion of the hydrogen sulphide from the filtrate by boiling, and titration of the acid with normal alkali. In this process any copper sulphate present as an impurity would of course be converted into sulphuric acid and similarly any copper acetate into acetic acid.

A weighed quantity of the substance was dissolved in 50 Cc. of 5 per cent. neutral sodium citrate solution by the aid of heat, the mixture diluted to 75 Cc. with water, heated to boiling, and the copper precipitated with hydrogen sulphide. The copper sulphide was filtered off, washed with hot water containing a little hydrogen sulphide, the filtrate boiled until odourless, and the acid titrated with normal potassium hydroxide, using phenolphthalein as indicator.* The sulphate (SO₄) present was calculated to sulphuric acid (H₂SO₄) and the amount of normal alkali necessary to combine with it deducted from the total alkali used. The remainder of the alkali was then calculated to percentage of citric acid radicle (C₆H₅O₇). The amount of citric acid radicle varied from 46.6 per cent. to 53.4 per cent. However, no determination of acetic acid was made in the specimen of Merck & Co., so that the acetic acid (present as copper acetate) is calculated as citric acid.

**Results.**—Merck brand: 1.2230 Gm. required 10.85 Cc. normal potassium hydroxide, equivalent to 55.45 per cent. citric acid radicle (C₆H₅O₇) ; 1.0469 Gm. required 9.28 Cc. normal potassium hydroxide, equivalent to 55.41 per cent. citric acid radicle ; average, 55.43 per cent. citric acid radicle. M. C. W. brand: 0.8651 Gm. of the material required 7.71 Cc. normal potassium hydroxide ; 0.8651 Gm. contains sulphate equivalent to 0.12 Cc. normal potassium hydroxide ; 7.71 Cc. normal potassium hydroxide —0.12 Cc. = 7.59 Cc. normal potassium hydroxide required to combine with the citric acid, equivalent to 54.87 per cent. citric acid radicle ; 1.1387 Gm. of the material required 10.127 Cc. normal potassium hydroxide ; 1.1387 Gm. contains sulphate equivalent to 0.159 Cc. normal potassium hydroxide ; 10.127 Cc. normal potassium hydroxide —0.159 Cc. = 9.9688 Cc. normal potassium hydroxide required to combine with the citric acid present, equivalent to 54.74 per cent. citric acid radicle : average, 54.80 per cent. citric acid radicle. P. W. R. brand: 1.0036 Gm. of the material required 7.974 Cc. normal potassium hydroxide ; 1.0036 Gm. contains sulphate equivalent to 0.494 Cc. normal potassium hydroxide : 7.974 Cc. normal potassium hydroxide —0.494 Cc. = 7.48 Cc. normal potassium hydroxide.

* The method is open to the objection that the copper sulphide does not invariably filter out readily, thus causing delay and possible oxidation to sulphuric acid.
potassium hydroxide required to combine with the citric acid, equivalent to 46.61 per cent. citric acid radicle; 1.0010 Gm. required 7.93 Cc. normal potassium hydroxide; 1.0010 Gm. contains sulphate equivalent to 0.492 Cc. normal potassium hydroxide; 7.930 Cc. normal potassium hydroxide — 0.492 Cc. = 7.438 Cc. normal potassium hydroxide consumed by the citric acid radicle, equivalent to 46.55 per cent. citric acid radicle; average, 46.58 per cent. citric acid radicle. Squibb brand: 0.4701 Gm. of the material required 3.765 Cc. normal potassium hydroxide; 0.4701 Gm. contains sulphate equivalent to 0.244 Cc. normal potassium hydroxide; 3.765 Cc. normal alkali — 0.244 Cc. = 3.521 Cc. normal potassium hydroxide required to combine with the citric acid, equivalent to 46.55 per cent. citric acid radicle; average, 46.58 per cent. citric acid radicle.

The analytical results are tabulated below. In the second table the sulphate (SO₄) is calculated to copper sulphate (CuSO₄•5H₂O), and the amount of copper contained in it is subtracted from the total, thus giving the copper combined as citrate.

* No determination of acetic acid was made in this specimen, hence the acetic acid present as acetate is here calculated as citric acid.

† Calculated from SO₄.
While our investigation is not sufficiently extensive to determine the formula for copper citrate as found on the market it seemed worth while to compare our findings with the published formulas.

The normal copper citrate of theory $\text{Cu}_x(\text{C}_6\text{H}_5\text{O}_7)_{2x}$ requires $1:2$ molecules of copper to $1$ equivalent of the acid radicle. This relation by weight is as $1$ to $1.98$.

In the salt, "$\text{Cu}_x\text{C}_6\text{H}_5\text{O}_7$" of the literature, having $2$ molecules of copper to $1$ of the organic radicle, the relation is as $1$ to $1.48$; while in the salt prepared by means of alcohol (Kämmerer) this relation is as $1$ to $1.78$. In the salts which we have examined this relation is expressed by the following figures: M. C. W., $1$ to $1.53$; P. W. R., $1$ to $1.43$; Squibb, $1$ to $1.44$. Since the specimen of Merck & Co., contains acetate which was not determined, the relation of copper to citric acid could not be calculated. An examination of the tabulated results shows that copper citrate of the market varies considerably in composition, and demonstrates the need for the adoption of some standard defining the limits for impurities.

After these examinations were completed the essential findings for each specimen were submitted to the manufacturer interested together with an offer to examine a specimen submitted directly by the manufacturer.

E. R. Squibb & Sons replied that they no longer listed the product.

Merck & Co., replied: "A negligible amount of Acetate is always present in this salt." A specimen sent by this firm was found to contain $34.9$ per cent. total copper and acetic acid* equivalent to $1.06$ per cent. copper acetate $[\text{Cu}(\text{C}_6\text{H}_5\text{O}_7)_{2} + 5\text{H}_2\text{O}]$. Upon drying at $100^\circ$ C. the specimen lost $5.3$ per cent. of its weight.

Results.—Loss at $100^\circ$ C.; $0.5012$ Gm. of the material lost $0.0272$ Gm., equivalent to $5.43$ per cent.; $0.5014$ Gm. lost $0.0262$ Gm., equivalent to $5.21$ per cent.; average, $5.32$ per cent.

Copper.—$0.5993$ Gm. of the material required $33.17$ Cc. tenth-normal sodium thiosulphate, equivalent to $34.91$ per cent. copper; $0.7055$ Gm. required $39.05$ Cc. tenth-normal sodium thiosulphate, equivalent to $34.93$ per cent. copper; average, $34.92$ per cent. copper.

Acetate.—The distillate from $5.2896$ Gm. required $5.48$ Cc. normal potassium hydroxide, equivalent to $0.05429$ Gm. copper acetate $[\text{Cu}(\text{C}_6\text{H}_5\text{O}_7)_{2} + \text{H}_2\text{O}]$, or $1.03$ per cent.; the distillate from $5.3050$ Gm. required $5.92$ Cc. tenth-normal potassium hydroxide, equivalent to $0.05864$ Gm. copper acetate, or $1.10$ per cent.; average, $1.06$ per cent. copper acetate.

* Acetic acid was determined as follows: Five grams of the material were placed in a distillation apparatus, $100$ Cc. normal sulphuric acid added and the mixture distilled to about $20$ Cc.; $200$ Cc. distilled water were then added, and the distillation repeated. The distillates were then united and titrated with tenth-normal potassium hydroxide using phenolphthalein as indicator, and the acetic acid found calculated to copper acetate.

1 Cc. $\frac{N}{10}$ KOH $= 0.009907$ Gm. $\text{Cu}(\text{C}_6\text{H}_5\text{O}_7)_{2} + \text{H}_2\text{O}.$
A specimen sent by the Mallinckrodt Chemical Works, and which was said to represent the product which that firm now sells, was found to contain 2.7 per cent. of water, 35.6 per cent. of copper, 55.5 per cent. citric acid radicle, and to be free from sulphate. This demonstrates that sulphate is not an unavoidable impurity in commercial copper citrate.

Results.—Loss at 100° C.; 1.0022 Gm. of the material lost 0.0271 Gm., equivalent to 2.70 per cent.; 1.0009 Gm. lost 0.0268 Gm., equivalent to 2.68 per cent.; average, 2.69 per cent. loss at 100° C.

Copper.—0.4146 Gm. of the material required 23.41 Cc. tenth-normal sodium thiosulphate, equivalent to 0.14774 Gm. copper, or 35.64 per cent.; 0.4006 Gm. required 22.54 Cc. tenth-normal sodium thiosulphate, equivalent to 0.142204 Gm. copper, or 35.50 per cent.; average, 35.57 per cent. copper.

Citric Acid Radicle.*—1.0005 Gm. of the material required 29.046 Cc. normal potassium hydroxide; 29.046 Cc. normal hydroxide —20 Cc. (the amount required to neutralize the added acid) = 9.046 Cc. normal alkali necessary to combine with the citric acid present. This is equivalent to 56.55 per cent. citric acid radicle. 1.0040 Gm. required 29.046 Cc. normal potassium hydroxide (9.046 Cc. consumed by the citric acid present), equivalent to 56.35 per cent. citric acid radicle; average, 56.45 per cent. citric acid radicle.

Powers, Weightman, Rosengarten Co. replied that they no longer had in stock any specimens of the particular lot which was examined in the Association laboratory. They reported that a specimen taken directly from their stock contained much less sulphate than the specimen examined in the Association laboratory. A specimen sent by this firm lost 6.3 per cent. of its weight at 100° C., contained 1.2 per cent. SO₄ and 34.1 per cent. copper.

Results.—Loss at 100° C.; 1.0053 Gm. of the material lost 0.0642 Gm., equivalent to 6.32 per cent.; 1.0043 Gm. lost 0.0626 Gm., equivalent to 6.23 per cent.; average, 6.28 per cent. loss.

Sulphate.—2.0051 Gm. of the material gave 0.0576 Gm. barium sulphate, equivalent to 1.19 per cent. SO₄; 2.0001 Gm. gave 0.0579 Gm. barium sulphate, equivalent to 1.18 per cent. SO₄; average, 1.19 per cent. SO₄, equivalent to 3.08 per cent. crystallized copper sulphate (CuSO₄ + 5H₂O).

Copper.—0.3827 Gm. of the material required 20.58 Cc. tenth-normal sodium thiosulphate, equivalent to 0.12986 Gm. copper, or 33.94 per cent.; 0.3205 Gm. required 17.36 Cc. tenth-normal sodium thiosulphate,

* As the copper sulphide when precipitated from this specimen by the method previously described could not be readily filtered, the method was slightly modified in order to obviate this difficulty. The weighed sample was dissolved in 20 Cc. of warm, normal sulphuric acid (instead of sodium citrate solution) and the determination completed as previously described, allowance being made in the calculation for the acid added.
equivalent to 0.10954 Gm. copper, or 34.19 per cent.; average, 34.06 per cent. copper.

The results obtained in the examination of the several specimens procured directly from the manufacturers, are summarized in the accompanying table:

While it is conceded that the entire absence of impurities cannot be demanded in commercial copper citrate, yet there is a product on the market which meets all reasonable requirements for purity. In view of this and in view of the variability in the purity of copper citrate as shown by the several examinations, the following provisional standards for purity and strength are recommended for the product:

Copper citrate should contain copper equivalent to from 34 to 36 per cent. of metallic copper.

If about 1 Gm. of copper citrate be dissolved in 20 Cc. of diluted hydrochloric acid, the solution diluted to 200 Cc. with hot distilled water, the mixture saturated with hydrogen sulphide, filtered, and the filtrate evaporated nearly to dryness on the water-bath, the residue should respond to the usual tests for citric acid.

If 0.5 Gm. of copper citrate be dissolved in 10 Cc. of diluted hydrochloric acid and 1 Cc. of barium chloride test solution be added, no turbidity should at once occur (limit of sulphate).

A solution of 0.5 Gm. of the salt in 10 Cc. of diluted sulphuric acid should not evolve any odor of acetic acid when boiled.

The salt should be free from nitrates, chlorides and carbonates.

Chemical Laboratory of the American Medical Association.

The Chairman: These papers are now before you for discussion. If no comments are to be made, we will pass on to the next one.

Mr. Beringer: Mr. Chairman, the Committee on the U. S. Pharmacopoeia have presented their report to the Section, in which are a number of principles to be acted upon. Action on those principles was delayed until copies were made. These copies are now here. I move that the recommendations offered by the Committee, and submitted at a previous session of this Section, be now approved by this Section, for adoption by the General Association.
The motion having been duly seconded was discussed at considerable length by Messrs. Stevens, Turner, Lyons, Eldred, Beringer, Dohme, Puckner, Vanderkleed, Kraemer and Kelly, and upon being put to a vote was declared lost.

MR. KRAEMER: I now move that these General Principles be referred back to the General Association, from this Section, without endorsement.

MR. TURNER: If I understand it right, these did not come from the General Session, but from a committee.

MR. BERINGER: My understanding is this: that the Committee on the Pharmacopoeia is a committee of the whole body, but this report was referred to the Scientific Section for consideration. If the American Pharmaceutical Convention does not send its recommendations to the Convention, there will be no outline for discussion. Now if we can agree upon some general lines, we ought to do it. That is the sole reason the Committee had for shaping up these recommendations.

THE CHAIRMAN: I think the motion made by Mr. Kraemer is quite logical, and is the correct one. It is evident that we, as members of this Section can not agree on this material as presented. This is presented by a Committee that was appointed by the Association to consider such matters, and coming from that Committee, as the consensus of opinion of its members, it will have just as much weight in the Pharmacopoeial Convention as if it came with the endorsement of the Association back of it. And after all is said and done, the Committee of Revision is entrusted with the revision of the Pharmacopoeia, and must act in accordance with their best judgment. If we refer these principles without endorsement to the general session, the general session will not doubt refer them to our delegates to the convention, and the delegates to the convention will then present them as the consensus of opinion of the ten men who have been specially appointed to consider this particular question; and they will receive the consideration that is rightfully due to them.

MR. KRAEMER: That report has already been received by the Association in general session, and has been referred to this Session for technical discussion. Now we say as a Section we appreciate the work that has been done on this thing, but we can not agree on certain details, and we refer the matter back to the general session to do with it as it sees fit. It is simply an opinion that the experts do not agree on these things—not that the report will not have its due weight. There is no slur intended—nothing of the sort.

MR. SCOVILLE: I think this Section ought to understand one thing, and that is, that in all probability any report of this kind would be referred simply in blank to the Revision Committee. At the last session of the convention there were a number of such reports sent in, and they were all acted on just in that one way. If the convention were to consider all such reports that came before it, they would be in session for a year. They will entertain nothing but direct motions from their delegates. Nothing but a direct motion in writing from a delegate will probably be entertained by this convention; and this is not a direct motion, and can not be received as such; it comes in too many forms for a single motion. The Revision Committee, however, will consider and report on this question—but not, I think, the convention.

THE CHAIRMAN: The question has been called for; and the question, as the Chair understand it, is that the report of the U. S. P. Committee be referred back to the general session, without recommendation.
Motion carried.

The Chairman: We will now resume the presentation of the papers; and the next one on the program is Dr. Roberts' paper on "A New Rack for Holding Separatory Funnels." Dr. Roberts is not here, so we will pass on to the next paper, which is by Mess. Engelhardt and Schmidt, and on the subject of "Scammony Resin."

By request Mr. Dohme read the paper.

SCAMMONY AND RESIN SCAMMONY.

BY H. ENGELHARDT AND M. R. SCHMIDT.

Considerable work has recently been done on the chemical and physical properties of the several substances generally classed as scammony resins. Guiges,* Cowie, † and Taylor ‡ have made important contributions to our knowledge of these bodies, but it appears that the end is not yet reached.

The whole subject is more complicated than would appear at first sight, and great confusion exists, especially in the minds of dealers, as to what is covered up by the terms scammony and resin scammony.

The U. S. P. recognizes as official two substances, scammony, which is the exudate obtained by incising the living root of Convolvulus Scammonia, and resin scammony, which is prepared by extracting scammony with alcohol, precipitating the resin with water, and drying at a gentle heat.

The French Codex recognizes the same substances.

The British Pharmacopoeia, on the other hand, describes virgin scammony, resin scammony and scammony root; the virgin scammony as used without further purification, and the resin scammony is made by extracting scammony root with alcohol. Consequently resin scammony of the British Pharmacopoeia is not necessarily identical with resin scammony of the U. S. P. or the French Codex.

Of late years there has appeared on the market another substance, the so-called Mexican scammony, prepared by extracting the root of Ipomea orizabensis. This substance is not yet official in any of the pharmacopoeias.

The subject is further complicated by the difficulty of procuring authentic samples. The dealers frequently confuse names, and judging by our analytical results, substitution very often takes place. As an example, one lot of root shipped as genuine Mexican scammony was labeled "Convolvulus Scammonia, Mexican," which is of course contradictory.

The work of Guiges dealt principally with the solubility of scammony resin in ether and the optical rotation. He found that some scammony resins were partly insoluble in ether, while the resin from Ipomea oriza-bensis is completely soluble in ether and can be used to adulterate true scammony, a statement, which, as will be shown later, is incorrect. He also called attention to the necessity of using ether of a definite degree of hydration and alcohol percentage when determining the solubilities.

As regards the optical rotation, for resin extracted from the gum resin (scammony) Guigues found a maximum specific rotation of $-24.5^\circ$. For resin extracted from the root, the rotation varied from $-18.5^\circ$ to $-23.5^\circ$.

The work of Cowie showed that the saponification value is a simple and accurate means of distinguishing true scammony resin from Mexican resin. Cowie also studied the solubility in ether.

Taylor has also made a rather extended study of the acid and saponification numbers, ether solubility, and iodine numbers of various scammony resins. According to his statement, however, all these resins were prepared by extracting the root with alcohol, and hence none of them can be regarded as U. S. P. products.

Cowie does not give any details as to the history of most of his resins, but it appears that most of them were commercial samples, or purified resins obtained from commercial articles. If his resins were prepared by purifying virgin scammony, they would come under the class of the U. S. P. resin scammony, but would not be official in the British Pharmacopoeia, and vice versa, if they were made by extracting the drug, they would be official in the British Pharmacopoeia and not in the U. S. P. This instance shows the difficulty of arriving at definite conclusions in these matters.

The chief result of Taylor's and Cowie's work has been to show that the saponification values for resins from Convolvulus Scammonia range around the number 238, while the saponification values of the resins obtained from the Mexican root are generally less than 190. Taylor, using U. S. P. ether, found that both the Mexican and true scammony resins, with the exception of one sample, were at least 99 per cent. soluble in ether. This does not agree with the statement of Cowie, who finds that true scammony resin is soluble from 96.4 to 100 per cent. in ether of a sp. gr. of 720, while three samples of the Mexican resins were dissolved only to the extent of 68.6 to 72 per cent. Cowie has directed attention to the varying solubility which will be found if the ether used in the different determinations is not perfectly uniform in quality. This fact may account for the discrepancies between Taylor's and Cowie's results. A more detailed discussion of this point will be taken up later.

The resins examined in this work were all purified according to the U. S. P. method, i.e., extracting with boiling alcohol, with precipitation of the concentrated extract by water and subsequent drying. In order to
insure more perfect drying, without the danger of overheating, all our resins were dried in the following manner. After thorough washing, the resinous mass was freed from inclosed water by stirring and draining. It was then dissolved in alcohol, filtered, and the alcoholic solution evaporated to a thick syrup, which was then poured on thin sheets of glass and dried at a temperature slightly below 100° C. The results show that the moisture content of resins dried in this way is no less than is found in those which have been dried by other methods. The alcohol was certainly eliminated, but it appears that a temperature above 100° C. is necessary to remove the water entirely. The U. S. P. direction to dry at "a gentle heat" therefore seems inadequate. *

The moisture determination was made by heating the powdered resin on a watch glass for one hour at 110° to 115° C. Our results are practically identical with those of Cowie and Taylor, and the same is true of the percentages of ash.

The determination of the acid number often offers considerable difficulty, on account of the dark color which the solution assumes almost immediately after the addition of any alkali. Recourse was finally had to the method of Marx: † 2 Gm. of the powdered resin are dissolved in a large flat-bottomed porcelain dish in about 100 Cc. of neutral alcohol and the titration made with ½ normal alcoholic potash and phenolphthalein. The solution of the resin is thus brought against a white background, in a thin layer, which facilitates the determination of the end point. Even with this aid, however, the determination is not always satisfactory, and little confidence can be placed in the accuracy of the results. An attempt to use x/4 barium hydrate solution was unsuccessful, since the color developed, if anything, was darker than that caused by the potassium hydroxide.

The saponification values were determined in the usual way, using x/2 caustic potash.

Ether solubilities were determined in both commercial and anhydrous ether. The commercial ether had a sp. gr. of .7182 at 25° C., while the anhydrous ether had a sp. gr. of .7106. It will be noted, as Cowie has already pointed out, that the ether solubility varies with the nature of the ether used.

A rather extended study of the iodine numbers was made. The method by Huebl was applied at first, but it was found to be impossible to obtain concordant results by it. The iodine numbers varied in some cases 100 per cent. when the different tests were allowed to stand for different lengths of time. Moreover, no definite end point could be found when titrating the excess of iodine with sodium thiosulphate and starch indicator. The

* The French Codex directs 45° C.
solution continually became blue within ten seconds after being decolorized, and this often continued during the addition of 3 to 5 Cc. of thiosulphate. This method was finally given up and the determinations were made according to the method of Wijs.* This method has proven itself to be so satisfactory that we can recommend it most highly, at least when working with these resins. The solution is prepared as follows: 9 grammes of powdered iodine are dissolved by the aid of heat in 500 Cc. of glacial acetic acid. Chlorine gas, washed through water, and dried by sulphuric acid, is then passed into the solution, using a capillary tube to insure more complete absorption. Thus the iodine is converted into iodine monochloride. The completion of the reaction is shown by the sudden disappearance of the dark brown color of the solution, and this end point is very easily seen. About \( \frac{1}{10} \) of a gram more of iodine is added, until the dark color of the solution is partly restored. This is done to prevent the solution containing an excess of chlorine. To make a determination, one gram of the powdered resin is put into a glass-stoppered 200 Cc. bottle, 10 Cc. of redistilled carbon tetrachloride free from carbon disulphide or oxidizable substance are added, and 25 Cc. of the iodine monochloride solution. After standing for one hour in the dark 20 Cc. of 10 per cent. potassium iodide solution are added and 50 Cc. of distilled water, and the excess of iodine titrated back in the usual way. The end point is very sharp and there is very little tendency for the blue color to reappear. One sample which was allowed to stand for 15 hours required only 0.3 Cc. more of tenth-normal thiosulphate solution to titrate the iodine which had separated.

The iodine numbers obtained by Wijs's method were in every case higher than those obtained by Huebl's method, even when the latter solutions were allowed to stand for 24 hours. Blank determinations are unnecessary with Wijs's method. The equivalent of 25 Cc. of the solution in terms of sodium thiosulphate solution is determined once for all, and the solution is so stable that subsequent blanks therefore are not necessary. The solution of iodine monochloride can be prepared in \( \frac{1}{2} \) hour, and for most oils and fats from 15 to 40 minutes is sufficient time for complete absorption of the iodine. The behavior of the scammony resins towards Huebl's solution led us to consider one hour as the minimum time necessary, but it may be said that no difference was found when the absorption was continued for \( \frac{1}{2} \) hour longer.

The optical rotations were determined with the decolorized resin in the following way: about 4 Gm. of the resin were dissolved in about 50 Cc. of alcohol, water added almost to turbidity, and the solution boiled for one hour with about 2 Gm. of animal charcoal using a reflux condenser.

See also the excellent article by Harvey, Journ. Soc. Chem. Ind. 21; No. 23, 1137- (1902).
After settling, the solution is cooled, and the liquid poured through a filter. A second treatment with animal charcoal generally suffices to give a solution which is almost colorless. After filtering 10 Cc. of this solution are removed by a pipette to a small tared beaker, evaporated to dryness, dried at 110° C. and weighed. Another portion of the solution is polarized in a 10-Cm tube.

In order to confirm the results of previous observers, and to orient ourselves regarding virgin scammony and Mexican scammony resin, the specimens marked I, II, III, and IV in the tables were prepared. Number I came to us labeled "Virgin Scammony, elect." In its physical appearance it agreed with the descriptions given in the text-books. It was of a greenish-brown color, very brittle, and its luster would have been classed as subresinous in mineralogy, since the fracture was almost without gloss. It was also of a granular or porous texture. No gross impurities were visible, such as pebbles, woody matter, etc. In our opinion, this sample was actually the exudate from Convolvulus Scammonia, which had possibly been freed from coarse impurities by fusing and straining.

A purified resin obtained by extracting a portion of I with alcohol, precipitating with water, etc., constitutes specimen II. Number II presented an appearance entirely different from I. It was of a yellowish-brown color, semi-transparent, not very odoruous, and its luster was markedly resinous.

III was prepared by percolating a lot of root which had been labeled "True Scammony Root." Microscopic examination bore out this statement.

IV was obtained by percolating a lot of drug identified as Ipomea orizabensis.

These samples were compared with three products marketed under the names of virgin scammony and scammony resins. Specimen V was labeled "Scammony Resin Virgin." Its appearance was totally different from that of I, its luster was perfectly resinous, its color dark brown and instead of being porous the pieces were perfectly homogeneous like ordinary resin. Its odor, moreover, was cheese-like. Judging from its appearance, and more especially from its physical and chemical constants, this sample was wrongly labeled. Before use it was purified in the usual way.

Specimen VI was labeled "True Scammony Resin," and in general appearance was identical with V. This sample had also been misbranded.

Sample VII was labeled "Resin Scammony." In it appearance it was like V and VI, but its odor was slightly like pepper. It was examined both in the ordinary state in which it was received, and after having been purified, the purified sample constituting specimen VIII. The results show that it was also made from the Mexican Root, and was therefore wrongly labeled.

The following results were obtained and are arranged in three tables.
Table I includes moisture, ash, acid, saponification and ester numbers. As stated before, the moisture content of these resins was not reduced by the method of drying adopted by us. The results agree perfectly with those found by Cowie and Taylor and no further comment is necessary, except to call attention to the high percentage of moisture in the commercial samples I and VII.

The percentage of ash is rather constant, and in all cases except I is well below the limit of 1 per cent. allowed by the U. S. P. for resin scammony. The percentage of ash found in I is also below the limit of 3 per cent. allowed by the U. S. P. for virgin scammony; this high percentage of ash confirms our belief that the resin had been only superficially purified by straining from gross impurities.

Nothing definite can be concluded from the acid numbers, as has already been stated by Taylor and Cowie. The saponification numbers, on the other hand, fall into two well-defined groups; I, II, III have saponification numbers which are considerably over 200. II, which may be taken as a representative sample of purified virgin scammony, has the value 236.6 which is in close agreement with the average of about 238 found by Taylor, Cowie and others. The saponification value of the other five samples range within narrow limits around the number 177, which is lower than the average saponification value obtained by Taylor and Cowie.

Table II shows the solubility in various solvents. The most important results are the solubilities in ether. Cowie and Guiges have, as already stated, directed attention to the necessity of using anhydrous ether in determining the solubility, and their results are fully confirmed by the present work.

Sample I, the most impure specimen of all, was soluble to the extent of 71.8 per cent. in dry ether but to the extent of 85 per cent. in commercial ether, thus passing the requirements.

Sample II, the purified resin prepared from I, was entirely soluble both in anhydrous and commercial ether. III was soluble to the extent of 96 per cent. in commercial ether, and by stretching the words "almost completely" might have passed muster as the U. S. P. article, although it was prepared by percolating scammony root. The other five specimens vary between 80 per cent. and 90 per cent. soluble in anhydrous ether. In this connection we must call attention to the phenomenon always noticed when dissolving Mexican scammony in ether. Using U. S. P. ether, containing varying amounts of water and alcohol, a part of the resin invariably separates as a varnish on the walls of the vessel. This does not take place with resin made from scammony or from scammony root, and this appearance can be used to detect Mexican scammony in the presence of a considerable quantity of true scammony resin. Using anhydrous ether, the insoluble portion assumes a granular form which on standing settles to the bottom as a sticky mass.
The portion insoluble in chloroform was generally gelatinous and rather dark in color.

We have already spoken of the difficulty encountered in determining the iodine numbers by the method of Huebl. For example, sample II after being allowed to stand for 4 hours gave an iodine number of 5.5; after standing for 15 hours this value had risen to 8.8 and another test which was allowed to stand for 24 hours showed only 8.22. Sample V, with Huebl's method gave 8.33 after five hours and 10.58 after fifteen hours, while the same resin by Wijs's method gave 11.6 in one hour. The average of our iodine values is slightly greater than the average of Taylor's. As can be seen from the tables, no definite relation exists between the variety of resin and the iodine value, and this method can not be used as a means of differentiating the resins. We wish, again, however, strongly to recommend the method of Wijs. It is convenient, rapid and accurate, duplicate determinations agree well, the end point is sharp, and work is considerably lessened by the fact that the solution is stable and blanks are unnecessary for each determination. The solution should be kept in a dark bottle, otherwise the acetic acid is likely to be substituted by the halogens and the solution will lose in strength.

The specific rotations also fall into two distinct groups. The values found for the resins known to be derived from Convolvulus Scammony are close to 24° while those for the Mexican resins are all over 31° Guiges, as mentioned before, was the first one to call attention to this fact. Our value of —25.98° for sample I is slightly higher than his maximum of —24.5° obtained for a specimen prepared in an identical manner, and our value of —24.24° for sample III is slightly higher than his limit of —23.5° for resin extracted from the true root. These determinations can be made with a considerable degree of accuracy, and the optical rotations furnish a valuable means of distinguishing the true and false resins. The specific rotation of the Mexican resin approaches the specific rotation of resin jalap, but the high price of resin jalap would prevent any adulteration of Mexican resin with the former.

It is a well-known fact that virgin scammony is getting to be a scarce article and it is practically impossible at the present time to obtain any quantities of the authentic substance. Moreover, all the work that has been done so far goes to show that the resin prepared by extracting the root of Convolvulus Scammony is practically identical with resin scammony prepared according to the U. S. P. directions from virgin scammony. We would suggest, therefore, if resin scammony is to be retained in the Pharmacopoeia that the Revision Committee make the resin extracted from the root official, as has been done in the British, Belgian and Italian Pharmacopoeias. On the other hand, if it can be shown by physiological experiments that the Mexican resin is identical in its action with true resin scammony, there seems to be no good reason why that cheap and abundant article should not replace the latter.

The Chairman: We have two papers here by Albert Schneider, one entitled “Some Nauseous and Otherwise Objectional Chinese Drugs Imported into the United States;” and the other on the subject of “Adulteration of Vegetable Drugs.” Mr. Schneider not being present, we will pass those papers, reading them simply by title.

This appears to bring us to the end of our business for this session; and if no member has any additional communications to present we will proceed to the next order of business, and install the officers—who are already in their respective positions, and to whom we will entrust the business for the ensuing year. I thank you, gentlemen, for your cooperation. I will now entertain a motion to adjourn.

Mr. C. E. Caspari: Before we adjourn, I think it is more than due the officers of this Section, for the brilliant way in which they have disposed of the very large number of papers, that this Section give them a sincere vote of thanks; and I make that motion.

Mr. Kraemer: I want to second that motion. I have always taken a special delight in the Scientific Section and regard it as the backbone of this Association. There was a time when it was thought the one might be the ruin of the other. I think this year...
the multiplicity of papers before this Section has shown that this Section can hold its own.

Mr. C. E. Caspari: I suggest that Mr. Puckner put the motion for a vote of thanks to the officers.

Mr. Puckner: Gentlemen, you have heard the motion, that a vote of thanks be extended to the Officers of the Section, for their very efficient work; all in favor of that motion will say Aye. (Motion unanimously carried.)

On motion the Section here adjourned.

Papers read by title.

THE DISTRIBUTION OF ALKALOIDS BETWEEN IMMISCIBLE SOLVENTS AND ITS BEARING UPON ASSAY PROCESSES.

BY ATHERTON SEIDELL.

[Hygienic Laboratory, U. S. Public Health and Marine Hospital Service, Washington, D. C.]

Distribution studies which have been made upon a large number of substances have shown that the constancy of the coefficients of distribution disappears at great dilution. Furthermore, with substances which have different molecular weights in the two solvents the proportionality exists only between the amount dissolved as single molecules in the one solvent and the square root of the amount dissolved as double molecules in the other solvent. The distribution of alkaloids between immiscible solvents has so far as I am aware received slight attention, consequently the following determinations were made for the purpose of obtaining some little experimental data upon this interesting subject.

The question of the effect of the distribution of alkaloidal salts between the immiscible solvents used in assay processes is of little importance, since these fall in the category of electrolytes and it is well known that in the case of electrolytes the proportionality of distribution exists only for the undissociated molecules which are present, and since dilution increases the dissociation in the aqueous layer much more rapidly than corresponding to the decrease in concentration, the constancy of the ratio of distribution disappears. For instance, if a sufficiently dilute aqueous solution of an organic acid be shaken out with an immiscible solvent only slight traces will be removed although the acid may actually be more soluble in the solvent employed than in water.

A number of experiments made with benzoic acid illustrate this point very forcibly. Four Gm. of ammonium benzoate were dissolved in 200 Cc. of water and 50 Cc. of this solution were acidified with 10 Cc. \(\frac{3}{4}\) H\(_2\)SO\(_4\) and shaken out successively with 10 Cc. of carbon tetrachloride. The amounts of benzoic acid in terms of ammonium benzoate recovered by each extraction were as follows:
It therefore appears that the relative amount of benzoic acid entering the carbon tetrachloride layer diminishes very rapidly with decrease in concentration, and that after the fifth extraction each succeeding operation yielded less than one-third the total available benzoic acid, thus demonstrating the theoretical impossibility of extracting all the acid by means of carbon tetrachloride. Further experiments made by adding increasing weighed amounts of benzoic acid to cylinders each containing equal volumes of water and carbon tetrachloride and rotating at 25° for one day confirmed the above results. With the addition of 0.5 Gm. C₆H₅COOH to 10 Cc. of H₂O + 10 Cc. of CCl₄, the amounts of acid in the H₂O and CCl₄ layers were as 5.84 is to 88.2, and when 0.1 Gm. C₆H₅COOH was used the ratio was as 13.4 to 83.0. The addition of acid to the aqueous layer resulted in diminishing the quantity of benzoic acid which it contained.

If now we consider the case of alkaloidal salts dissolved in water and shaken with immiscible solvents or as is customarily applied in practice, the extraction of alkaloids from organic solvents by shaking with dilute acid, we find that the conditions for a part of the alkaloidal salt remaining in the organic layer are even more unfavorable than with benzoic acid and carbon tetrachloride. The alkaloidal salts are for the most part easily dissociated and are furthermore extremely slightly soluble in the majority of the ordinary immiscible solvents, and therefore should remain wholly in the aqueous layer. In order, however, to obtain experimental confirmation of this point a series of determinations was made as follows:

Increasing weighed amounts (0.0060 to 1.000 Gm.) atropine sulphate, morphine sulphate and quinine bisulphate were placed in cylinders to which were then added equal volumes (15 Cc. each) of water and chloroform. After a two-day period of rotation at 25° a 10-Cc. portion of each chloroform layer was removed and evaporated to dryness in a weighing bottle, the residues calculated for the total of 15 Cc. of CHCl₃ varied in the case of atropine sulphate from 0.002 to 0.0003 Gm.; in the case of morphine sulphate from 0.0006 to 0.0010 Gm., and in the case of quinine bisulphate from 0.0001 to 0.0004 Gm. Thus a practically negligible amount was found in all cases.

Similar results were obtained a few years ago by A. Simmer (Arch.
THE DISTRIBUTION OF ALKALOIDS.

Pharm. 244, 672-84) who, at the suggestion of Professor E. Schaer, of Strassburg, studied the behavior of alkaloidal salts towards immiscible solvents, especially chloroform. The experiments were made by shaking out aqueous solutions of the salts, acidified with definite amounts of acid with the solvents in question. Negligible amounts were obtained with the more basic alkaloids, but appreciable quantities with those less basic in character.

In the cases of the three salts employed in the preceding experiments the differences in their solubilities in water and chloroform are very great as illustrated by the following table prepared from the values quoted by the U. S. P. In this table the values for chloroform are not the reciprocals of the figures given in the Pharmacopœia, since it is probable, although not certain, that weight parts are there referred to, and in the present case the amount per given volume of chloroform is desired. The calculation to this basis has therefore been made for the three salts above named and also for strychnine nitrate.

These results show that although the distribution in the mixture of water and chloroform to which an excess of the salt was added is nearly equal to the ratio of the solubilities in the two solvents separately, with lowering of concentration the relative amount which enters the chloroform layer diminishes very rapidly.

The experiments which were made with alkaloids were carried out in

* This quantity of salt was more than enough to saturate both layers, consequently the excess remained undissolved between the two layers.
exactly the same manner followed for the alkaloidal salts, viz., increasing weighed amounts of alkaloid were placed in glass-stoppered cylinders, each containing 15 Cc. of water and 15 Cc. of Kahlbaum chloroform. The cylinders were rotated at 25° C. for two days and 10 Cc. portions of each of the upper layers and of each of the lower layers were evaporated to dryness at not over 60° C. in weighing glasses. The residues were dried in a vacuum desiccator containing concentrated sulphuric acid to constant weight. The amounts were calculated to grams per 15 Cc. of each layer. It will be noted that the sum of the amounts found in the two layers is slightly greater in most cases than the quantities originally added. The fact that pure alkaloids dissolved in chloroform gain in weight when evaporated, due probably to retained chloroform, has been known for some time and is no doubt the cause of the present discrepancies. These differences are in themselves of no great importance in the following experiments, since it is only the relative amounts actually present in equal volumes of the two layers which are of most interest. The results are as follows:

The residues from the aqueous layers were tested with Mayer's and Wagner's alkaloidal reagents and found to give the characteristic reactions for alkaloids. It is therefore evident, as was to be expected, that a distribution which is out of all proportion to the ratio of the solubilities of the alkaloids in water and chloroform separately, does actually take place, and furthermore that with increasing dilution this disproportion is rapidly augmented. The individual solubilities of the two alkaloids as calculated from the values quoted by the U. S. P. have the following ratios:

In the present case we see that although atropine is really 426 times as soluble in chloroform as in water when determined separately; with solu-
tions of approximately the concentration encountered in assays, the amount which goes into the chloroform layer may be only 12 to 25 times the amount remaining in the aqueous layer, thus giving the possibility of an error of 4 to 8 per cent. of the actual amount present. It will, of course, be objected that assay methods require repeated extractions with fresh portions of the immiscible solvent, but when it is remembered that the efficiency of each new portion of the solvent diminishes with the decrease in concentration, and furthermore that the time factor for reaching equilibrium during any one extraction is often not considered, and also that incomplete separation of the layers may occur, it is evident that these several sources of error are worthy of more consideration.

The fact that in distribution ratios we are dealing with spatial concentrations should certainly be emphasized in alkaloidal assays. The effect of a given 10 Cc. portion of chloroform is diminished directly in proportion to the volume of the aqueous layer which is being extracted. The question as to the advantages of many extractions with a small volume of the immiscible solvent as compared with a smaller number with a larger volume of the solvent should be studied.

Although the few experiments are not sufficient to use as a basis for many very broad conclusions in regard to the errors of the present-day assay processes which may be due to the distribution of alkaloids between immiscible solvents, they do call attention to the fact that this question is worthy of the very serious consideration of all who wish to develop alkaloidal assay methods to a higher state of perfection.

THE U. S. P. MELTING-POINT REQUIREMENTS.

C. A. MENGE, PH. D.

Division of Pharmacology, Hygienic Laboratory, U. S. P. H. and M. H. S.

Among the many needs of revision in the U. S. P. few are more urgent and more important than the melting-point requirements. This assertion seems to me to be justified by many reasons. The very general use of the melting-point determination as a means of identifying and as a test for the purity of a compound, the great confidence that is usually placed by the rank and file of chemists in the melting-point determination for the purpose to which it is applied, and the possible simplicity and convenience of method that may be applied in the great majority of cases for the reasonably reliable determination of this constant, would seem to place the melting-point determination among the most important tests in the standardization of any class of pure chemical compounds—particularly organic compounds.

The present legal status of the U. S. P., however, demands that the various tests prescribed therein for the standardization of pharmacopœial products should be so refined as to insure reasonable agreement in the results obtained by different manipulators working independently upon the
same product; and such a demand is not too exacting if the U. S. P. standard is to command any respect.

Unfortunately the melting-point requirements as at present prescribed by the Pharmacopoeia are deplorably incapable of any such degree of refinement—hence the imperative necessity for revision. In fact the whole subject of melting-points, in so far as any generally recognized or standard procedure is concerned, seems to be in a chaotic condition. An examination of the chemical and pharmaceutical literature in its bearing upon this subject will frequently disclose remarkable divergence—sometimes of astounding magnitude—in the values published as the melting-point of the same compound. Such a condition tends to undermine the confidence that the usual chemical or pharmaceutical training has taught most of us to feel in the reliability and simplicity of determinations of this constant.

It also strikingly suggests the urgent need of a careful review and investigation of the subject of melting-points in general and particularly in application to the U. S. P. where, through the operation of the Pure Food and Drugs Law, a definite and dependable standard has become imperative.

The causes of divergence in the published melting-point values for the same compound are doubtless several. The principal cause, however, seems to consist in the great variety of methods and procedure used by different operators in making the determinations, including such associated details as rate of heating, stirring, emergent-stem correction, etc.,—the partial or complete regulation or neglect of which offers wide range of opportunity for variation in manipulation with more or less corresponding variation results. In almost every laboratory the method of procedure applied in determining this important constant differs in greater or less degree from that of every other laboratory.

Other factors which are more or less conducive to divergence in melting-point values involve variation in the physical condition of the compound, such as the degree of adherent moisture, the size of individual particles, and of course the amount, and probably the kind, of impurity.

That the use of different methods, and variation in physical condition constitute real causes of divergence in the results of melting-point determinations of the same compound has been conclusively demonstrated by the work of such investigators as Landolt,* Reissert,† Tyrer and Levy,‡ Pawloff,§ and others.

Another factor which it seems to me contributes in no small degree to the discord in this subject is the widely varying conception among different chemists as to what the melting point really is. It is variously defined as that temperature at which it is just completely melted; or the mean

---

† Ber., 23 (2) (1890).
temperature of the range over which melting occurs. Some maintain that the term "melting-point" is misapplied, that it is purely theoretical, and that what we actually and invariably observe in practice is a melting range and not a melting-point.

In view of these facts it becomes a simple matter to point out the defects in the melting-point requirements of the present Pharmacopœia, and in a large measure at least, to suggest the remedy.

The Pharmacopœia prescribes no uniform method and procedure for the melting-point test. Each individual is free to select or devise whatever method may suit his fancy—a liberty which, as indicated by the excellent work of Tyrer and Levy,* involving comparative tests with nine different methods, may produce results for the same product showing divergence as great as 6° C., even though the condition of the compound and other details of procedure in the different cases were identical.

The present requirement is also defective in that it permits the operation of varied individual conception as what constitutes the melting-point, thereby conducing to further divergence in results.

And finally it is inconsistent in specifying a melting-range in some cases, while for most compounds it requires literally a melting-point—the latter being impractical, it seems to me, even for the purest compounds obtainable, and, in application to a standard which avowedly permits a certain degree of impurity, it is impossible.

Obviously, if the melting-point is to be of any value whatever as one of the pharmacopœial tests for a standard product, it is essential that all radical causes of divergent results should be eliminated. A perfect melting-point requirement for compounds of pharmacopœial standard is probably not possible at this time, but it seems certain that a very considerable degree of order may be evolved from the present chaos by the next Committee on Revision of the U. S. P. through the adoption of a carefully defined official method, including specific directions covering all details connected with a melting-point determination, and a clear, unmistakable definition of the melting point.

In co-operation with the present committee of Revision the Hygienic Laboratory has recently been conducting an investigation upon pharmacopœial melting-points for the purpose of selecting or devising a method and determining a general procedure which could be recommended for official adoption, and by means of which to standardize the melting-points of pharmacopœial compounds. In approaching this work it was not considered feasible to experimentally test a great variety of methods; nor indeed was such a time-consuming procedure necessary, for the specifications laid before us by the Committee on Revision, calling for the utmost simplicity, availability, and economy consistent with reasonable

---

* Loc. cit.
efficiency, made possible the elimination by inspection of practically all methods, except one or two which were considered to offer promise.

The method finally adopted consists of one of the capillary-tube variety, more or less modified to meet specific conditions as they developed. It involves the use of a simple round-bottom straight glass tube of about 30 mm. internal diameter and about 100 mm. long, flaring slightly at the top like an ordinary test tube. This tube or container is fitted with a stirring device, which any one can make in a very few minutes from a piece of small-sized, thick-walled capillary glass tubing of such length that a double bend above the top of the container brings the outer end of the stirrer within easy reaching distance of the hand for convenience in manipulation. When in use the container is filled with a suitable bath to a depth which will permit of such an immersion of the bulb of the thermometer that the upper end of the bulb will be 2 to 3 cm. below the surface of the bath and the lower end of the bulb about equally distant from the bottom of the container.

For melting points up to 150° C.—or even to 180° C.—pure concentrated sulphuric acid was considered the most suitable and satisfactory bath. When fresh it can be used at much higher temperature, but then its irritating fumes make it decidedly objectionable. After very considerable experimentation no bath could be found suitable for work at temperatures much above 200° C., which was not more or less objectionable because of fuming. This difficulty, however, was found to be effectively overcome by a slight modification of the apparatus, which consisted in fitting the container with a cork, perforated for the thermometer and for the stirrer and with two or three small vents at the edge to avoid excessive pressure. With this modification, a very pure grade of cotton-seed oil, freshly distilled paraffin, certain mineral oils, and a few other organic substances could be conveniently used up to 300° C. or over; but they soon become colored and have to be frequently renewed. A bath was finally adopted consisting of a mixture of pure concentrated sulphuric acid and potassium sulphate in definite proportions as recommended by Mülliken.*

In my experience this bath, contrary to the claims made for it, fumes at high temperatures almost as badly as the pure sulphuric acid. With the simple cork modification the fumes would char the cork and quickly spoil the bath, but by attaching a disk of thin asbestos to the bottom of the cork and including a glass tube in the perforation for the stirrer, both the fuming and the charring were effectively overcome and the bath could be used as high as 350° C., or even to 370° C., with perfect convenience and safety. In all cases where the cork modification was applied the stirrer, in order to avoid inconvenience in attaching the capillary tube to the thermometer, was made in two parts, the first part extending through and

THE U. S. P. MELTING POINT REQUIREMENTS.

about one-half inch above the cork; the second part being the remainder of the stirrer as first described. The two parts are easily joined, with ample security, by means of a small piece of small bore rubber tubing. The advantage of such an arrangement in connection with the cork hardly needs further discussion.

A list of 37 of the more important pharmacopoeial compounds was selected upon which to test the method just outlined and to begin a tentative standardization of their melting points. The compounds selected were at first considered to belong only to that class whose melting-point determination by a capillary-tube method offers no complication. I believe, however, that the application of this method to all other classes (such as fats, waxes, etc.) involves only modification in details and procedure and not any material change of apparatus. Furthermore, I can see no objection to applying it as a modification of Landolt's method in those cases where it would seem feasible and desirable to determine the melting-point or freezing-point of a compound by using a comparatively large amount, with the thermometer dipping directly into the substance. These points remain to be determined by further experimentation.

In the course of the work the value and utility of the melting-point when accompanied by decomposition became seriously questioned and compounds of this type were placed in a separate group for subsequent special investigation, thereby reducing the list for immediate investigation to 23 compounds.

The purpose of the work made it extremely desirable that a market sample from every manufacturer of each product should be obtained. To that end we entered into correspondence with several manufacturing firms but their extreme conservatism in giving information on this point soon disclosed the impracticability of the plan and we were forced to adopt the unsatisfactory alternative of considering that every sample in the market bears the label of the firm that makes it. Acting upon this alternative we were able to obtain, in most cases, 5 to 8 different samples of each compound. From 4 to 8 or more determinations of the melting-point were made on each of these samples according to the following procedure:

A small portion of the compound was ground in a mortar to a fine powder and dried in an ordinary desiccator over sulphuric acid for at least 24 hours. It was then introduced into a thin-walled capillary tube, of not less than one mm. nor more than two mm. diameter, until the material in the bottom of the tube formed a column two or three mm. high. The tube was then attached to a standardized thermometer, in such a manner that the sample was centrally located along the side of the mercury bulb, and lowered to position in the bath. The container was then heated by direct application of a small Bunsen flame, the temperature being raised at a rate merely consistent with reasonable caution (about 20° to 30° C. per minute) until within 20° to 25° C. of the melting-point. It was then
definitely regulated so as to maintain as nearly as possible a uniform rise of 3° C. per minute until the compound showed definite signs of melting when the rate was changed to 0.5° C. per minute. Constant stirring was applied throughout the experiment. The temperature range over which the substance was definitely observed to be melting was recorded as the melting-point. In this connection it was found that the point of initial melting might be variously determined by different individuals, or even by the same individual under different conditions, and it was therefore necessary to fix upon some characteristic behavior which would insure reasonable uniformity in this particular. After much experimentation, following the procedure outlined above, it was considered that the behavior could be defined, within reasonably narrow limits, as that temperature at which any point in the column of material was observed to collapse against the side of the tube.

Correction for the emergent stem of the thermometer was applied in all cases. To experimentally determine this for each experiment was obviously impracticable. A series of corrections for each of the two standard thermometers used were made independently at different times by two individuals. The average results obtained were plotted in a curve on coordinate paper and from this curve the emergent stem correction at any temperature could be determined by inspection. The error thus introduced in the final results, because of possible subsequent variation in room-temperature, is insignificantly slight and in most cases is doubtless less than the error that may result from slightly varied manipulation in different measurements of the correction. In fact the latter may be considerable and for this reason it would seem very desirable, if feasible, that official thermometers be prescribed as a part of the official method. Official corrections could then be determined and published in a table or curve thus eliminating another drawback to real standardization of U. S. P. melting-points.

The melting-points of the 23 compounds referred to having been determined, all samples were then subjected to the more important and specific of the other Pharmacopœial tests to determine their standard.

In the following tabulation each value given in the column under Hygienic Laboratory represents the average of all determinations on all corresponding samples of standard grade. When two or more values are found in this column under the same compound it indicates that different samples of standard grade showed consistent differences in melting-point and were therefore averaged separately. Such a condition is significant and suggests either that the same percentage of different kinds of impurity has a markedly different effect on the melting-point or, that the melting-point determination is a more effective method for detecting slight variations than other Pharmacopœial tests. In any case the fact constitutes a complication in melting-point standardization which remains to be overcome.
It is also true that in connection with a few compounds minor details of the work remain to be completed and the values here given may therefore be slightly affected.

In general, however, I believe these results are as exact and reliable as could reasonably be required, but it is certainly desirable that the results obtained by any method should be duplicated by several operators, applying exactly the same procedure, before being adopted as the U. S. P. official requirement.

The official melting-point requirements of six different pharmacopoeias for the same compounds and the values given in the common and more important sources of the chemical and pharmaceutical literature are added in the table for the purpose of comparison. A study of the comparative data in several instances will serve to further emphasize the need of investigation and standardization of melting points. At the same time, it should be recognized that the compounds here included represent the simplest to which the melting-point test can be applied, and also that the remarkable concordance sometimes found in the various official requirements does not necessarily indicate experimental duplication of the determinations.

* May be slightly affected by minor details of manipulation formulated after these values were determined.

† The behavior on melting, although quite uniform, of five different samples of this compound was very unsatisfactory. Re-melting indicates that the first melting is accompanied by slight decomposition, which does not become vigorous, however, until above 250°. It should therefore be further investigated with compounds which decompose on melting, but many careful determinations on different samples furnish uniform results which are included in this table for the striking commentary they suggest on the present U. S. P. requirement.
At the present time three species of strophanthus are used, viz.: strophanthus Kombé, strophanthus hispidus, and strophanthus gratus. While the glucoside obtained from the first two varieties occurs as a more or less colored varnish, the glucoside obtained from strophanthus gratus is crystalline. Inasmuch, however, as the last mentioned variety is on the market to a small extent only, the other two are used exclusively. In the pharmacopoeias at our disposal we find that strophanthus Kombé is official in the U. S., German, Hungarian, British, Swiss, Austrian and Danish pharmacopoeias. The Dutch and Swedish do not specify Kombé, but from the text it can be understood that strophanthus Kombé is recognized. The Spanish allows both Kombé and hispidus, while in the French Codex and the Italian and Belgian pharmacopoeias, the hispidus variety is official.

No species is mentioned in the Pharm. Japon.

To differentiate the two varieties, Kombé and hispidus, the sulphuric acid test is prescribed, which is best carried out by either soaking the seeds in water, removing the seed-coat and treating the endosperm with concentrated sulphuric acid, or by making a cross section of the seed and treating this in the same way, a more or less pronounced green color will be produced in case of Kombé seeds varying in intensity with the amount of strophanthin present in the seeds, while hispidus and gratus seeds do not produce this color.

Schaub (Apoth. Ztg., 1908, p. 920), recommended that the concentrated sulphuric acid be replaced by a weaker acid, i.e., an 80 per cent. acid, to avoid any charring which might be produced by the use of concentrated acid. This latter method is adopted by the Hungarian and Danish pharmacopoeias; according to various authors, however, concentrated sulphuric acid does not cause a charring.

The sulphuric acid method was further modified by G. Sharp (Pharm. Journ., 1906, 11, 258), who proceeds, as follows: Cut the seed in four parts, moisten these with sulphuric acid, sp. gr. 1.094, and heat for one minute, when a green color will be produced. This method, however, has no advantage over that with concentrated sulphuric acid, which as may be mentioned here is adopted by most of the new pharmacopoeias; only the Italian and Belgian pharmacopoeias giving no directions for the color test.

Various methods for the determination of strophanthin in strophanthus have been devised. Of the older ones, those of Fraser, Elborne, and Barclay may be mentioned. About ten years ago (Drugg. Circ., 1900), these methods were tried in this laboratory, and it was found that the last mentioned method gives the best and most concordant results. This method was later modified by Fromme, and described in the Geschaefts-
bericht von Cæsar & Loretz, 1906; Fromme also found that the factor
given by Barclay for the ratio of strophanthin to strophanthinidin is not 2.74
but 2.187, thus reducing the amount of strophanthin obtained by Bar-
clay’s method considerably.

Another assay method was recommended in the Jahresbericht der Phar-
macie, 1905, p. 28, and is carried out as follows: After removing the fat
from the crushed seeds with petroleum ether, the seeds are dried again and
extracted for three hours with 90 per cent. alcohol. The alcoholic solu-
tion is then filtered, the alcohol evaporated and the residue extracted with
water. To the aqueous solution a few drops of lead subacetate solution
are added and after shaking well the mixture is filtered. From the filtrate
the glucoside may be isolated (1) by precipitating with tannic acid, de-
composing the tannate by heating with lead oxide, extracting the dry lead
oxide mixture repeatedly with alcohol and precipitating the strophanthin
from the alcoholic solution by ether, or (2) by removing the excess of lead
in the filtrate by gradually adding ammonium sulphate, filtering and salt-
ing out the strophanthin with a large excess of ammonium sulphate. The
precipitate thus formed is treated with alcohol and the glucoside precipi-
tated from the alcoholic solution with ether. The process of recovering
the strophanthin by these two methods gives low results, due to an una-
voidable loss of the glucoside.

Another method was recommended some years ago by E. W. Männ
(Pharm. Journ., 1906, 2, 93), who proceeds as follows: 100 Gm. of
powdered seeds are deprived of fat by extracting with petroleum ether
and the resulting powder, free from fat, is extracted with hot alcohol. The
alcoholic solution is evaporated, the residue taken up with water and the
solution saturated with subacetate of lead. The excess of lead is removed
from the filtrate with sodium sulphate and the filtered solution evaporated
with 10 Gm. of fine sand. The mixture, after perfect drying, is extracted
with boiling amyl alcohol. The amyl-alcohol solutions are then evaporated
at a temperature not exceeding 60° C. and the residue weighed. This
method, besides being very circumstantial, and requiring a large amount of
material, does not give accurate results.

In the following investigation we, therefore, applied Barclay’s method
with Fromme’s modification. This method is carried out as follows: 7
Gm. of finely crushed seeds are heated in an Erlenmeyer flask of 200 Cc.
contents with 70 Gm. of absolute alcohol for one hour, and after cooling,
any alcohol lost by evaporation is replaced. After thorough mixing, 50.5
Gm. of the alcoholic liquid, equal to 5 Gm. of the seed, are filtered into a
porcelain dish of 9 to 10 Cm. diameter, the alcohol evaporated on a water-
bath, and the residue extracted with petroleum ether. The petroleum
ether is filtered through a plain filter of 5 Cm. diameter and dish and filter
washed with petroleum ether. The insoluble residue on the filter is then
rinsed with 5 to 8 Gm. of boiling water into a porcelain dish, the contents
of the latter heated to boiling, mixed well with 5 drops of solution of sub-acetate of lead and about 0.2 Gm. of infusorial earth. The liquid is then filtered into an Erlenmeyer flask of 100 Cc. contents and the dish and filter washed with boiling water until the filtrate no longer tastes bitter. To the filtrate five drops of hydrochloric acid are added and the mixture heated to boiling on an asbestos plate over a small flame for two hours. Any water lost by evaporation is replaced by adding distilled water, until the contents of the flask weigh 20 Gm. After cooling, the liquid is shaken with 10 and 10 Cc. of chloroform, which is filtered into a tared Erlenmeyer flask of 100 Cc. capacity. The aqueous liquid is again heated for one-half hour and, after cooling, again shaken out with 10-10-10 Cc. of chloroform. The combined chloroformic filtrates are then distilled and the residue dried in a desiccator to constant weight. The weight obtained multiplied by 2.187 gives the amount of strophanthin in 5 Gm. of the seeds. For the sulphuric acid reaction we adopted the following method, also originated by Fromme: 20 seeds are softened for one-fourth hour in cold water and, after removing the hulls, are put upon a porcelain or glass plate and treated with one drop of concentrated sulphuric acid; a green color of the endosperm should be produced in all the seeds.

In addition to this test we also applied the method of treating the seeds with an 80 per cent. sulphuric acid.

We have examined seven samples of strophanthus seed, of which two were marked "hispidus" and one was unmarked, and have obtained the following results:

<table>

As will be seen from the above results, only three samples consist entirely of Kombé seed, among these the one which was marked "Hispidus." Two of the samples contained Kombé seed to a large extent, while
one of them marked Hispidus and the other not specified are apparently Hispidus seeds mixed with a small percentage of Kombé seed.

As regards the percentage of strophanthin in the samples, all of them must be considered as fair commercial samples. A good Kombé seed, however, should contain at least 7 to 8 per cent. of strophanthin. As none of the samples comes up to this standard, and as inferior products are liable to be found on the market, standardization of strophanthus seed seems to be justified.

The foregoing claim, that seeds with at least 7 per cent. of strophanthin should be used, is made by Reyden also (Farmaceutisk Tidskrift, 1910, Nos. 4 and 5). This author found that the best results in identifying the seeds are obtained by Schaub's method and that Fromme's method for the estimation of strophanthin gives very concordant results.

Very interesting experiments were made by Hefter, (Ther. Monatshefte 1909, page 45) more or less confirming the above statements, for the details of which the original article should be consulted.

By numerous experiments on frogs it was found by Focke that the amount of strophanthin found by Fromme's assay method is proportional to the physiological activity, a statement which was later verified by other investigators.

We, therefore, come to the conclusion that the new Pharmacopoeia should adopt a standard and an assay method for strophanthus seed.

We desired to make comparative tests with Strophanthus gratus, but unfortunately we have not been able to procure samples of this variety.

THE RESULTS OF A FEW CRUDE DRUG ASSAYS.

BY HENRY J. GOECKEL.

The assays reported here were made since 1906 or since the Eighth Revision of the Pharmacopoeia was published and will therefore aid in giving an idea of the quality of the crude drugs offered within the period since then.

In assaying drugs the writer has from time to time noticed a factor to which little attention appears to be given by many assayers. This is the difference in the amount of moisture contained in various lots of drugs. Though the U. S. P. does not place any stress upon this, it ought to be noted.

The divergent results obtained by different assayers and by pharmacists who take the trouble to assay their supplies can in the writer's opinion be at times accounted for by the fact that through changed conditions in transit or in storage the moisture content of the drugs varies. This can readily occur without the sample showing any outward difference. In the instance of drugs of low alkaloidal contents this will be most noticeable.

For the most part goods are not packed in moisture-proof containers
and freight handlers are not particular or interested enough to see that the freight is well protected during rainy weather. Likewise the writer has often noted some of the most reliable supply houses have packed drugs in paper containers and then used not only moist but actually wet excelsior to fill the cases in which the goods were shipped.

In my experience the effect which the moisture contents may have on the results of assays was well shown by a lot of belladonna root. This when received gave 0.493 per cent. of mydriatic alkaloids by the U. S. P. process. This was the result of a duplicate assay as are all the results here given. The same sample from which the assay was made was dried for a few days and was then found to yield 0.534 per cent. of alkaloids, more than sufficient to pass it.

Acacia.
Of four lots of acacia in powder examined the ash yield was for No. 1 quality, 3.05 per cent., and 3.09 per cent., for No. 2, 2.8 per cent. and for No. 3 quality it was 3.17 per cent.

Belladonna Leaves.
Of six lots of belladonna leaves examined, two were above the requirements of 0.35 per cent. of mydriatic alkaloids and four were below.

\[
\begin{align*}
1 & \ldots 0.532 \text{ per cent. of alkaloids.} & 3 & \ldots 0.283 \text{ per cent.} & 5 & \ldots 0.247 \text{ per cent.} \\
2 & \ldots 0.391 & & 4 & \ldots 0.254 & 6 & \ldots 0.2416 \\
\end{align*}
\]

Belladonna Root.
One lot examined before drying \ldots 0.493 per cent. of alkaloids.
After \ldots 0.534 \ldots 

Codeine Phosphate.
Four samples of codeine phosphate examined gave respectively 70.399 per cent., 72.43 per cent., 75.41 per cent. and 89.04 per cent. of alkaloid base.

Ipecacuanha.
Of eight lots of ipacac root examined, only one came up to the requirement of 2 per cent. of alkaloids, four were above the 1.75 per cent. standard, and three were below this. The samples were of the entire root as directed by the U. S. P.

\[
\begin{align*}
1 & \ldots \text{before powdering 2.1 per cent. of alkaloid.} & 5 & \ldots 1.783 \\
2 & \ldots 2.048 & & 6 & \ldots 1.721 \\
3 & \ldots 1.955 & & 7 & \ldots 1.416 \\
4 & \ldots 1.836 \text{ per cent. of alkaloids.} & 8 & \ldots 1.266 \\
\end{align*}
\]

Jalapa.
Four lots of jalap examined all came up to the U. S. P. requirements.
THE RESULTS OF A FEW CRUDE DRUG ASSAYS.

1. 1.231 per cent. 10.980 per cent. 12.211 per cent.
2. 1.487 " 7.487 " 9.3495 "
3. 1.401 " 7.02 " 8.421 "
4. 1.566 " 8.159 " 9.5257 "

Malt Extract.
One lot of malt extract examined gave

Alcohol (absolute).............4 per cent. Diastasic strength........6.751 per cent.

Magnesium Carbonate.
One lot of magnesium carbonate examined was not clearly soluble in acetic acid, gave a slight flocculent precipitate, and showed considerable calcium and iron.

Pancreatin.—Eleven lots of pancreatin from original containers gave results as follows:

<table>

Seven passed the U. S. P. requirements and four did not.
The following reported assays were made since 1906 on eighty-seven lots of opium as submitted in New York.

The process of assay was that of the U. S. P. with the exception that twenty cubic centimeters of lime water more than directed by the Pharmacopoeia was used.

Of the forty-two lots of dried gum assayed, one yielded less than 11.4 per cent., namely 10.08 per cent. of crystallizable morphine. Of the forty-five lots of moist gum three were below 10 per cent. and one of these below 9 per cent.

The dried gum yielded as follows:

<table>

The maximum was 13.657 per cent., the minimum 8.898 and the average was 12.385 per cent. of morphine.

THE RESULTS OF SIXTY COCA ASSAYS.

BY HENRY J. GOECKEL.

In view of the fact that this meeting of the American Pharmaceutical Association is a pre-revision of the United States Pharmacopoeia gathering, and as the standard of ether-soluble alkaloid requirement in coca by the present revision of the U. S. P. (8th) is considered too low by some of the members of this Association, the results of sixty assays of lots of coca leaves examined since 1905 for Schieffelin & Co. by the writer will perhaps be of interest.

The results tend to confirm the claim that the present requirements are too low.

Of all the assays only two (2) were below 0.612 per cent. of ether-soluble alkaloids; one, an Erythroxylon Coca, yielded 0.558 per cent., and the other, an Erythroxylon truxillense, yielded 0.582 per cent. of alkaloids.

Thirty of the assays were on lots of Erythroxylon Coca, of which I have not the commercial name. They were probably Huanuco leaves and represent more than 1500 bales of leaves.

In each instance where the number of bales is known to the writer the fact is stated.

The maximum was 0.888 per cent., minimum 0.558 per cent., average 0.687 per cent. of truxillone.
The maximum was 1.11 per cent., minimum 0.532 per cent., average 0.780 per cent. alkaloids.

The preceding assays were made according to the following method:

Twenty (20) grams of well-ground coca leaves are agitated for one (1) hour in a mechanical shaker with kerosene 200 Cc. and a few Cc. of dilute ammonia. Then extract in percolator to 500 Cc. with kerosene. Percolate is then extracted with four portions of HCl (15 pts. to 200 pts. H₂O). The acid liquor is washed with three portions of ether, then made alkaline with a slight excess of ammonia, extract with ether 20 Cc., 15 Cc., and 15 Cc., evaporate at 65 to 70 degrees Centigrade in a tared beaker. The amount of \( \frac{x}{10} \) H₂SO₄ required is estimated by dividing the weight by 0.03. Dissolve the alkaloids in ether, add a slight excess of \( \frac{x}{10} \) H₂SO₄, evaporate off the ether, add 3 drops of cochineal indicator, titrate excess of \( \frac{x}{10} \) H₂SO₄ with \( \frac{x}{10} \) NaOH, multiply the difference between the acid and the alkali by 0.03 to get the weight of the alkaloid calculated as cocaine.

**Identification of Methyl Alcohol in Ethyl Alcohol.**

By H. Englehardt and H. W. Jones.

The numerous methods which have been devised for the identification of methyl alcohol in ethyl alcohol may be grouped as follows:

1. Those methods in which the identification is made by certain reactions given by those substances which usually accompany methyl alcohol, i.e., acetone, etc.
2. Those methods in which the alcohol is subjected to a complete oxidation by chromic acid or other oxidizing agents.
3. Those methods in which the methyl alcohol is oxidized to formaldehyde by applying red-hot copper or platinum spirals.
4. Those methods in which only a partial oxidation of the mixed alcohols is carried out by the action of oxidizing agents such as chromic acid or potassium permanganate.

The methods of the first group must be considered as entirely unreliable, inasmuch as comparatively pure methyl alcohol (Colonial spirit), free from acetone or other products derived from the destructive distillation of wood, can easily be obtained.

A few methods of this group may be mentioned here. That originated by Reynolds (Pharm. Journ. 1864, 5, 272; 1865, 6, 292), and later on modified by Tuck (Pharm. Journ., 1865, 6, 215, et seq.), depends on the property of acetone to prevent the precipitation of mercury salts by caustic potash. The one by Guyard (Bull. Soc. Chim., 1879, 297), is based on the fact that wood alcohol forms iodoform in the cold with alkaline potassium-iodide iodine solution.

Watanabe's (Journ. Pharm. Society Japan, 1909, May) method depends
on the formation of a flocculent precipitate which is produced by the addition of Nessler's reagent to grain alcohol containing methyl alcohol.

Carette's (Journ. Pharm. et Chim., 1909, 481) method is carried out as follows: The liquid under examination is distilled, and to 5 Cc. of the first distillate 5 Cc. of water and 3 Cc. of ammonia water are added, and then 1 Cc. of tincture of iodine (French codex), when by the acetone present in the methyl alcohol iodoform will be formed after allowing the liquid to stand, with occasional shaking, in diffused light.

Habermann and Österreicher (Zeitsch. Analyt. Chem., 1901, No. 11), found that methyl alcohol decolorizes potassium permanganate much more easily than ethyl alcohol, which statement, however, was contradicted by Schoorl (Zeitsch. Anal. Chem., 1902, 426), who found that the permanganate is more difficulty decolorized by pure methyl alcohol than by pure ethyl alcohol.

To the second group belongs the method of Dupré (Analyst. 1876, 1), who oxidizes the mixture of methyl alcohol and ethyl alcohol, with chromic acid; while under certain conditions the methyl alcohol is oxidized to carbonic acid and water, ethyl alcohol is oxidized to acetic acid. The mixture is distilled and the distillate is titrated with caustic potash, and from the amount of caustic potash used the percentage of ethyl alcohol is calculated. The difference between the amount of the mixture taken and the alcohol calculated from the acetic acid is considered as methyl alcohol.

Thorpe & Holmes (Proc. Chem. Soc. [Lond.] 1903, 285), distill the mixture of ethyl alcohol and methyl alcohol with potassium chromate and sulphuric acid. They found that when the process is properly conducted, the methyl alcohol is oxidized to carbonic acid and water while the ethyl alcohol is oxidized to acetic acid. The carbon dioxide is absorbed in a bulb filled with soda lime, and from the increase in weight the wood alcohol can easily be estimated.

The method of oxidizing the mixture of methyl and ethyl alcohol by treating it, in proper dilution with water, with a red-hot copper spiral, was first applied by Mulliken and Scudder (Am. Chem. J. XXI, 266; ibid., XXIV, 444), and later on modified by Prescott (Pharm. Arch. 4, 86). The method, which is also official in the U. S. P., depends upon the fact that methyl alcohol is oxidized to formaldehyde, while ethyl alcohol is oxidized to acetaldehyde. The latter, by boiling, can easily be removed, and with the resulting solution of formaldehyde or its polymers various reactions for the detection of formaldehyde with various reagents can be made.

While Prescott in his original method proposed to treat the formaldehyde solution with phloroglucine solution and caustic potash, by which a red color is produced when all the acetaldehyde has been properly eliminated, Haigh (Pharm. Rev. 1903, No. 10) uses a diluted phenylhydrazinehydrochloride solution, sodium nitroprussiate solution and strong caustic potash,
by which a blue to green color is developed. The U. S. P. uses, as is well known, the resorcinol solution. Kahn (D. A. Apoth. Ztg. through Pharm. Ztg. 1905, 651) mixes the formaldehyde solution, obtained by the oxidation of the methyl alcohol with copper, with milk containing a trace of ferric chloride, and underlays the mixture with concentrated sulphuric acid. In the presence of formaldehyde a purple color will be produced at the zone of contact. Other workers have used morphine-sulphuric acid as reagent, which without doubt is a very delicate reaction for this aldehyde. Phloroglucine, according to various investigators, is almost as sensitive towards formaldehyde as the morphine-sulphuric acid, but the color produced by the former is not as distinct as that produced by the latter. According to Fendler & Mannich (Arb. pharm. Inst. Univ. Berlin, 1906, 249), \( \frac{1}{100} \) Mg. of formaldehyde can be identified in a dilution of 1 to 100000 by applying a solution of morphine in concentrated sulphuric acid, and it is not necessary to remove the acetaldehyde entirely, as this gives only a yellow coloration with the reagent.

The process for oxidizing the mixtures of methyl alcohol and ethyl alcohol by a red-hot copper spiral has, according to several investigators, a number of disadvantages, one being that a part of the ethyl alcohol is also reduced to formaldehyde, another one that by eliminating the acetaldehyde by prolonged boiling a part of the formaldehyde is lost, and further, that by this method only 2 to 5 per cent. of methyl alcohol can be estimated in the grain alcohol.

However, when the oxidation is carried out carefully, only an infinitesimal amount of formaldehyde is formed from the ethyl alcohol. When, further, morphine-sulphuric acid or phloroglucine are used as reagents the presence of 1 per cent. of methyl alcohol can be shown with the former and of 0.5 per cent. with the latter.

It is necessary, however, to make a blank test with pure ethyl alcohol when phloroglucin is used, for better comparison of the color. By boiling the mixture rather permanent and distinct colorations can be obtained.

By the resorcinol test the color obtained with alcoholic liquids containing less than 2 per cent. of methyl alcohol cannot be distinguished from that obtained with pure ethyl alcohol. With percentages of methyl alcohol of 2 per cent. or over, however, the appearance, upon rotating the test tube, of reddish flocks, as described by Scudder (Journ. Am. Chem. Soc., 127, 892–906 (1905)), serves to indicate the presence of this alcohol, since with pure ethyl alcohol these flocks are not obtained.

Much better results have been obtained by oxidizing the mixtures of the alcohols with oxidizing agents like chromic acid or permanganate. The first ones to replace the oxidation with a red-hot copper spiral by permanganate were Sanglé-Ferrière and Cuniasse (Ann. Chim. anal. appl. viii, 82), who used potassium permanganate for the oxidation. This method was modified by Scudder & Riggs (Journ. Am. Chem. Soc., xxviii,
1202), who proceed as follows: Add to the alcohol under examination 0.5 Cc. of concentrated sulphuric acid and 5 Cc. saturated solution of potassium permanganate. After two minutes sufficient sulphur dioxide solution is added to decolorize the liquid and the mixture boiled until the odor of acetaldehyde and sulphur dioxide has disappeared; then the resorcinol test is applied.

Fendler & Mannich (loc. cit.), later on used the following method: 10 Cc. of the liquid under examination are heated in a flask of 50 Cc. contents provided with a condensing tube, which is bent twice at an angle of 90° C. and has a length of 75 Cm., until 1 Cc. of the distillate is obtained. To this 4 Cc. of 20 per cent. sulphuric acid are added, and the mixture transferred to a wide test tube. With thorough cooling and constant shaking, one gramme of finely powdered potassium permanganate is then added. When the liquid is almost decolorized, it is filtered through a small dry filter into a test tube. The liquid is boiled for 20 to 30 seconds, cooled, and 1 Cc. of the decolorized liquid mixed with thorough cooling with 5 Cc. of concentrated sulphuric acid. To the cool liquid 2½ Cc. of a freshly prepared solution of 0.2 Gm. of morphine hydrochloride in 10 Cc. of concentrated sulphuric acid are added, and the mixture allowed to stand for 20 minutes at room temperature. If the original preparation contains at least ½ per cent. of wood alcohol the liquid is colored intensely violet or red-violet. Alcohol or mixtures of alcohol and ether may be examined directly without distillation; tincture of iodine is treated, before being distilled, with 5 Cc. of water and 2 Gm. of sodium thiosulphate; preparations containing ammonia have previously to be neutralized. This method is said to indicate methyl alcohol in the proportion of 0.5 to 1 per cent.

The oxidation of the mixtures of the alcohols by potassium chromate and chromic acid was introduced by Wolf (Ann. chim. anal. appl. 4, 183), whose method was later on modified by Trillat (Compt. rend. cxxvii, 237). This method depends on the formation of methylal when methyl alcohol is oxidized by potassium chromate and sulphuric acid, which gives, with dimethylaniline, tetramethylamidodiphenylmethane, a blue-colored substance.

Vorisak (Journ. Soc. Chem. Ind. xxviii, 823) proceeds, as follows: 0.5 to 1 Cc. of alcohol or alcoholic distillate is placed in a 6-inch test tube, 1 Cc. chromic acid solution is added and the mixture diluted to 4 or 5 Cc. After adding 2 or 3 pieces of pumice, the test tube is connected with a condenser of special design and distilled into another test tube. When 3 or 4 Cc. of liquid have passed over or when only about 0.5 Cc. remains, the condenser is detached and rinsed with about 2 Cc. of water into the receiving tube. To the distillate are added 1 drop of ferric chloride solution and two drops of albumin solution, and after mixing the liquid is underlaid with sulphuric acid. If more than 5 per cent. methyl alcohol is present
a violet zone appears at once. 1 to 5 per cent. is shown in one minute. Less than 1 per cent. requires several minutes. Ethyl alcohol gives no color. With organic impurities a yellow to reddish color is often obtained, but no violet. The color is intensified on warming.

By this test 0.001 Gm. methyl alcohol in 1 Cc. of the ethyl compound could be detected. The solutions used for this test are the following: Chromic acid solution containing 0.8 per cent. CrO₃ free from H₂SO₄.

Albumin solution. White of one fresh egg mixed with 50 Cc. of water, filtered and preserved with a few drops of chloroform. Pure milk answers nearly as well. (5 drops.) Ferric chloride solution, 0.4 per cent.

Voisenet's (Zeitsch. Unt. Nahr. u. Gen. 1907, 653), method depends on the fact that formaldehyde gives in presence of an albuminoid and of hydrochloric acid containing nitrates a violet color. The same reaction is given by methylal and methyl-diethylate, which products are obtained by the oxidation of methyl alcohol with potassium bichromate and sulphuric acid; while the oxidation products obtained from ethyl alcohol by this oxidation method do not give a coloration. He proceeds by diluting 10 Cc. of the liquid under examination to 50 c.c. with water, adding 5 Gm. of powdered potassium bichromate and 30 Cc. of 20 per cent. sulphuric acid and allowing the mixture to stand for one hour. Then 30 Cc. of the mixture are distilled, which are discarded. 4 Cc. of the next 20 Cc. of distillate are mixed with 0.1 Cc. albumin solution and 15 Cc. of hydrochloric acid containing nitrous acid.

The mixture is then shaken until the coagulated albumin is dissolved and then heated on a water bath to 50° C. If the alcohol to be examined contains methyl alcohol a violet color will be produced, varying in intensity with the amount of methyl alcohol present.

The albumin solution is prepared by beating the white of an egg with \( \frac{3}{5} \) water, the hydrochloric acid containing nitrous acid by mixing 200 Cc. of hydrochloric acid with 1 Cc. of a \( \frac{6}{10} \) per cent. potassium nitrite solution.

Hinkel (Analyst. xxxiii, p. 417), replaces potassium permanganate and chromic acid with ammonium persulphate, and proceeds as follows: Add to 1 Cc. of the mixture to be examined, 0.8 Gm. of ammonia persulphate and 3 Cc. of dilute sulphuric acid (1 to 5) then make up to 20 Cc. with water and distil over 5 different portions of 2 Cc. each. The first two portions, which contain acetaldehyde, are rejected, the remaining three are tested for methyl alcohol by adding to the liquid a few drops of \( \frac{1}{2} \) per cent. morphine hydrochloride solution and underlaying the mixture with concentrated sulphuric acid.

In case methyl alcohol is present a violet zone will be produced at the contact point of the liquids.

In this paper only those methods which have appeared since the publication of the U. S. P. have been described and tested, omitting those in
which the identification of the methyl alcohol depends on admixtures usually contained in methyl alcohol.

The experiments were confined principally to those methods in which the oxidation is carried out in acid medium with potassium permanganate, bichromate or ammonium persulphate. Our experiments have shown that the best and comparatively the simplest method is that of Hinkel, by which less than 1/2 per cent. of methyl alcohol in ethyl alcohol can be proven. The reactions obtained by the other methods were more or less inconclusive. The method of Fendler & Mannich is uncertain and difficult to carry out, while with that of Voisenet we were unable to obtain any definite color reaction. While writing this paper an article appeared by Schmidt & Gaze (Arch. d. Pharm. 1909, No. 7), in which directions for the detection of methyl alcohol in galenical preparation (tinctures, fluidextracts, etc.) which contain volatile oils are given. For particulars the original paper should be consulted.

Since the writing of the above paper an article translated from the Polish of A. Bukowski has appeared in the Pharmazeutische Post (XLIII, No. 14, Feb. 18, 1910), in which the author reviews the various methods for the identification of methyl alcohol, and recommends a modified form of the Fendler-Mannich method. He proceeds as follows: 2 to 3 Cc. of the liquid are mixed with 10 Cc. of 15 per cent. sulphuric acid and the mixture cooled with ice. Then potassium permanganate is added in small portions (.1 to .2 Gm.) and shaken well after each addition. After a slight pinkish color remains permanent the turbid liquid is filtered several times through a small filter until a perfectly clear or slightly reddish filtrate is obtained. The decoloration may be facilitated by gentle heating, and if the liquid should again become turbid it is filtered again through a filter. For the detection of the formaldehyde the morphine-sulphuric acid reaction is used and in addition to that the method originated by Mentzel: Add to 1 Cc. of the mixture .01 Gm. of phenylhydrazinehydrochloride and shake until the latter is dissolved. Then add one drop of a 10 per cent. iron chloride solution and finally 10 to 15 drops of concentrated sulphuric acid, when in presence of formaldehyde a carmine-red color will be produced.

We have tried this method, but the results obtained were inconclusive and quite as unsatisfactory as those obtained by the Fendler-Mannich method.

LABORATORY NOTES ON THE PHARMACOPEIA.

JOHN R. RIPPETOE.

It is a proverbial saying that practice makes perfect, and it might just as truly be said that criticism and suggestion (help to) make perfect. The past few years have seen many comments on the 8th Revision of the Pharmacopoeia, especially as to the standards and assay processes. They
have been criticised, changes advised and entirely new methods and standards suggested. This paper will do a little of each.

It has been said that the Pharmacopoeia went into too much detail in outlining some of the methods. With these statements I wish to disagree, for it is lack of detail in many cases of minor importance probably, but still sufficient for two chemists working in different laboratories, or in fact in the same laboratory, to obtain entirely different results, due to their interpretation of the methods and in applying the same. Many standards are left entirely to the judgment of the analyst, such as “a faint turbidity,” “moderately cool place,” or “a very slight residue.”

It is true the Pharmacopoeia is not a text-book, but no matter how well the analyst may be trained in other lines of chemical analysis, he will apply his own methods of manipulation, where the method is not clearly outlined. When he assays opium for example, how vigorously will he agitate the flask every 10 minutes, how will he transfer the opium to the flask for the second maceration, how will he evaporate carefully, and what is a moderately cool place? It is very doubtful if the analyst agitating the flask every 10 minutes will get the same result as the analyst using a mechanical shaker.

The following notes are taken from the writer’s laboratory note-book, and are observations made in conducting the routine work of the analytical laboratory of a pharmaceutical manufacturing house.

**Tartaric Acid.**—We have examined a number of samples, but recall only one sample that was entirely free from sulphuric acid. The U. S. P. limits this impurity and requires that an aqueous solution 1–10 should “show but a faint turbidity.” In our opinion we have had a great many samples that showed what we considered much more than a “faint turbidity.” I think it would be much more satisfactory to make this test quantitative, determining by comparison with a standard sulphuric acid solution. The amount present is small and may not affect the medicinal value, but causes sufficient difference of opinion to make trouble.

**Dilute Hydriodic Acid.**—The comments under tartaric acid would apply to this preparation, as to the limit of sulphuric acid.

**Aconite.**—In the assay of this drug it would be much more practicable to exhaust the drug with ether or a chloroform-ether mixture, either complete or using an aliquot portion, since with the present U. S. P. method powdered aconite requires considerable time to exhaust with a menstruum of alcohol and water, owing to the very slow percolation, and the subsequent evaporation is very likely to cause decomposition of the unstable alkaloid aconitine.

Filtering the acid mixture of the evaporated residue through filter paper is very tedious. We find that by filtering the liquid through cotton, and then washing the acid solution with ether, and rejecting the ether, expedites the manipulation of the assay. The ether solution of the extracted alkaloid
should be decanted into another vessel before evaporating, leaving any water that may have collected behind. Rinse the vessel with several small portions of ether, and add to the original solution. This precaution should be applied to all ether solutions of alkaloids, as it is almost impossible to avoid a few drops of water getting in from the stem of the separator.

As to washing the acid mixture with ether and rejecting the ether, I find it a great advantage to wash all acid extractions with a portion of the volatile solvents being used, and rejecting previous to rendering alkaline for the final extraction of the alkaloids. This is of special advantage in the assay of the leaf drugs like belladonna, hyoscyamus, coca, etc., and their preparations, where some coloring matter may have been held by the acid solution due to an emulsion or not a perfect separation.

Balsam Peru.—Owing to the sodium hydroxide solution dissolving a portion of the ether, the results obtained for cinnamine content are usually higher than the amount actually present. Weighing off 5½ grammes of ether is also a very tedious process, especially if the room is very warm. This process can be simplified by completely extracting the sodium hydroxide mixture with several portions of ether. Following out this method will give about 5 per cent. less cinnamine than the U. S. P. method, but a more correct determination of the amount present. Gentle heat should be stated "at any temperature between 32° C. and 38° C.," for many may not know the term is defined on page liii. The temperature is very important.

Capsicum.—We have examined samples of this drug for alcoholic extract, and have found several that contained less than 12 per cent., while an average sample should contain at least 20 per cent.; showing a possible partial removal of the alcohol-soluble matter. It would seem desirable to have an alcoholic extract standard or some such test for this drug.

Yellow Wax—Beeswax.—Determining the saponification value in the presence of paraffin adulteration, the heating should be done by boiling at least one hour with the flask connected with a return condenser, otherwise the value found is likely to be too low and variable, owing to incomplete saponification.

Coca.—Very few samples of this drug assay less than 0.8 per cent. ether-soluble alkaloids, therefore, it might be advisable to raise the standard from 0.5 per cent. to 0.8 per cent. We have had samples of Truxillo leaves assaying as high as 1.2 per cent. of the ether-soluble alkaloids. The assay process is somewhat simplified by using 5 grammes of the drug instead of 10, as the exhaustion of the drug with the ether chloroform mixture is much easier accomplished.

Cocaine Hydrochloride.—The melting-point requirement for this drug should be deleted from the U. S. P., as there is practically no true melting point; it is, more properly speaking, a decomposition point, which depends entirely upon the rapidity of heating the sample. Under the test for
limit of cinnamyl-cocaine, 3 drops of \( \frac{8}{10} \) potassium permanganate should be charged to read 0.18 (0.185) Cc., since 3 drops is an indefinite amount. Also, under test for limit of isatropyl-cocaine, 4 drops of ammonia water should be charged to read 0.25 (0.245) Cc., and cold distilled water should be described by a definite temperature. We are in the habit of using water at 15 degrees centigrade. A six-ounce wide-mouth bottle is to be preferred to a beaker in carrying out this test.

**Cresol.**—The required specific gravity for this article, namely 1.036 to 1.038 is within too narrow limits. I note 17 samples having the following densities at 25 degrees C., 1.034, 1.0348, 1.0385, 1.0336, 1.0324, 1.0331, 1.0332, 1.0345, 1.0360, 1.045, 1.032, 1.050, 1.038, 1.0376, 1.0344, 1.031, and 1.0385.

The lower densities indicate the presence of meta or para cresol, and since meta cresol is considered the most valuable of the three as a germicide, it would seem the lower gravity cresol would be preferred. Very few of the above samples were soluble in 60 parts of water.

**Reduced Iron.**—The assay process for this preparation is not satisfactory since it is inclined to give low results, owing to the iodine not completely dissolving or acting upon all of the iron.

**Fluidextract of Aconite.**—The comment under aconite as to filtering the acid mixture from the evaporated residue and washing with ether, applies to this preparation.

**Fluidextract of Gelsemium.**—This preparation should have an alkaloidal standard and assay process for determining the same. The following method based upon Webster's method has given very satisfactory results. Transfer 15 Cc. of the sample to a 200-Cc. measuring cylinder, add 10 Cc. water, 5 Cc. sodium hydroxide T. S. and 150 Cc. chloroform-ether mixture 4-1. Shake the cylinder frequently during one hour, set aside and when the chloroform-ether layer has become clear, note the volume, and draw off two-thirds, representing 10 Cc. of the sample. Transfer to a separator and extract the alkaloids with 1 per cent. sulphuric acid; make the acid solution alkaline with sodium hydroxide T. S., and extract the alkaloids with chloroform-ether mixture 4-1, finally extracting the alkaloids from the volatile solution with 5 Cc. \( \frac{8}{10} \) sulphuric acid diluted with 10 Cc. water, shaking the separator for two minutes, and after drawing off the acid solution, wash the volatile solution with several portions of water, finally collecting the acid solution and washings and titrating excess acid with \( \frac{8}{10} \) potassium hydroxide, using about 20 drops cochineal indicator.

**Fluidextract of Ipecac.**—The comment under fluidextract of aconite applies to this preparation.

**Fluidextract of Nux Vomica.**—It is more practical to transfer the 10 Cc. of sample to a separator, add 4 Cc. ammonia water, and extract with chloroform and proceed according to the U. S. P. method, than to evap-
orate to dryness, etc., as directed. I find the use of sodium nitrite or nitrous acid the only practicable way of completely oxidizing the brucine.

Fluidextract of Pilocarpus.—The assay process for this preparation is needlessly complicated, since, as satisfactory results can be obtained by extracting 10 Cc. of the fluidextract directly with chloroform, after the addition of 2 Cc. ammonia water, and continuing as under the U. S. P. process. The sand and extract residue is very tedious to transfer from a dish to a flask, and the chloroformic extraction of the residue is likely to prove troublesome owing to emulsification.

Fluidextract of Podophyllum.—This preparation should have a resin standard and assay process for determining the same. A chloroformic extract standard would possibly be the most practicable.

Fluidextract Sanguinaria.—This preparation should have an alkaloidal standard and assay process for determining the same.

Glycerite of Hydrastis.—This preparation should have an alkaloidal standard and assay process for determining the same. The U. S. P. method for fluidextract of hydrastis is a satisfactory method.

Oil of Cajeput.—The assay process for determination of cineol is very unsatisfactory. We have found the resorcin method as proposed by Schimmel & Co. (Report Schimmel & Co., Oct., 1907, p. 47) or A. Ph. A. Proceedings, 1908, p. 324) very satisfactory, and think it would be a more desirable method than the present one.

Oil of Cinnamon.—Oil of cinnamon and oil of cassia should be considered as two distinct oils, since these two oils are distinguished commercially, the former being about ten times more expensive than the latter, and consequently subject to adulteration with the cheaper variety. Oil of cassia is darker in color, the odor less delicate and the specific gravity often exceeds the limit 1.055 at 25° C.

Oil of Eucalyptus.—The comment under oil of cajeput applies to this oil.

Oil of Lavender Flowers.—An optical rotation standard should be given for this oil. We have examined samples of this oil that complied with the U. S. P. requirements, but were dextrogyrate and of inferior odor, while oils of a desirable odor were always laevogyrate.

Oil of Peppermint.—The test for absence (?) of dimethyl sulphide should be changed from after a “short time,” to after ten minutes. Oils that are known to be rectified will give a white film if allowed to stand long enough, and a “short time” is somewhat indefinite.

Cod Liver Oil.—Under iodine value 0.3 Gm. should be changed to 0.2 Gm., since 25 Cc. of the iodine mixture is not sufficient when 0.3 Gm. of the oil is taken, and is inclined to give results that are too low.

Oil of Tar.—The specific gravity for this oil is too low. The following six samples were claimed by the distillers to the best they could produce.
Specific gravities respectively 0.9582, 1.0340, 0.9943, 0.9749, 0.9574, 0.9897. It would seem desirable to go back to the old standard or better yet have a high and low limit.

Oil of Turpentine.—The test for absence of petroleum benzin, kerosene or similar hydrocarbons is not satisfactory, as the layer in samples known to be pure will measure more than 0.35 Cc.

Opium.—In the assay of this drug agitating the flask every 10 minutes during 3 hours does not prove very satisfactory, as the results are usually lower than may be obtained by the use of a mechanical shaker. A laboratory that has much alkaloidal assay work to do, should be provided with a mechanical shaker if it is desired to obtain a thorough agitation of the flask. It is also a great time-saver.

It is more expedient to transfer both filter and moist opium back to the flask and use a new filter for the second filtration. It should cause no trouble by increasing the bulk in the second filtration if a light filter paper is used. Careful evaporation is accomplished on a water-bath containing boiling water. A moderately cool place is obtained by using an ice box (refrigerator), which gives a temperature ranging between 10-15° C. A temperature above this should be avoided, as it is inclined to cause a heavy deposit of impurities.

Pancreatin.—Owing to the variable composition and freshness of milk, determining the converting power is not very satisfactory. It would seem advisable to remove this test from the Pharmacopoeia. The starch should be more clearly defined by stating the kind of starch to be used, although corn starch is possibly understood.

A method for drying the starch should be given, or possibly better use moist starch allowing for the moisture present previously determined by drying in a current of dry air. Two drops of \( \frac{\infty}{18} \) iodine, should be changed to read 0.12 Cc. and four drops of the warm converted starch solution to read 0.25 Cc. since two and four drops are indefinite amounts.

Pepsin.—Owing to the variable composition of eggs, it is an advantage to use a standard pepsin for carrying out a blank assay on the coagulated albumen, in determining the proteolytic power of the sample under examination.

The standard pepsin is obtained by testing it on several different eggs, and requiring that it should not leave a deposit of undissolved albumin measuring more than 1 Cc. on a majority of the eggs; hence, if the sample is found to leave a deposit measuring 2.5 Cc., and the standard pepsin leaves a deposit measuring not less, the sample is passed as satisfactory.

Compound Effervescent Powder.—This is a very extensively used preparation, and it would seem desirable to have an assay process for determining the presence of the proper amount of potassium and sodium tartrate. The following method gives very satisfactory results. Ignite one Gm. of the powder, representing the potassium and sodium tartrate
and sodium bicarbonate mixture, thoroughly at a red heat, and extract the residue, with boiling distilled water until the washings cease to react with methyl orange T. S. The mixed filtrate and washings should require for complete neutralization, not less than 16.2 Cc., nor more than 16.8 Cc. (16.5 Cc.) $\frac{3}{4}$ hydrochloric acid.

Soft Soap.—The test for limit of free alkali gives variable results, depending upon the length of time in obtaining the aqueous solution, temperature and amount of phenolphthalein indicator added. If, after the apparent discharge of the red tint has been obtained, two more drops of indicator are added, the red tint appears again and will reappear each time more indicator is added. A more satisfactory determination is obtained by dissolving 5 Gm. of the sample in 50 Cc. of neutral ethyl alcohol, then adding 25 Cc. of water, and stirring thoroughly to take up any insoluble residue. 1 Cc. of phenolphthalein indicator is then added and sufficient $\frac{8}{10}$ oxalic acid to discharge the red tint, which should not reappear upon the addition of more indicator. This preparation should be required to contain not less than 40 per cent. fatty acids, and a test should be given for determining their source, as cottonseed oil is extensively used in making this soap.

Spirit of Ammonia.—The specific gravity of this preparation should be taken at 15 1/2° C., as it is almost impossible to take the specific gravity at 25° C. by means of a pycnometer at least, owing to the liberation of ammonia gas at the higher temperature.

Sugar of Milk.—The test for absence of cane sugar remains very unsatisfactory. One Gm. of the sample will leave more than 0.03 Gm. of residue indicating the presence of cane sugar, but negative results are obtained when other tests are applied. The following test will show the presence of less than 1 per cent. of cane sugar. Mix 2 Cc. each of oil of sesame and hydrochloric acid, to which add 0.5 Gm. of the sample and shake for 30 seconds. A distinct red color, which may require a few minutes to develop, indicates the presence of cane sugar.

Terebene.—Absence of more than a trace of resinous substances should be determined quantitatively. I note four samples containing respectively 1.69, 1.79, 0.92, and 1.60 Gm. in 100 Cc. Is this a very slight residue?

ADULTERATION OF VEGETABLE DRUGS.

A SUMMARY.

BY ALBERT SCHNEIDER.

When the Federal and several State pure drug laws went into effect it was confidently expected that there would be a very appreciable falling-off in the adulteration of drugs of all kinds. It was believed that gross criminal adulterations would be rare occurrences indeed. In this our fond hopes are experiencing a great disappointment, for drug adulteration is at
ADULTERATION OF VEGETABLE DRUGS.

this time practiced to an alarming degree. This is certainly true as far as vegetable drugs are concerned. It is true that the pure drug work and the administration of the pure drugs laws is as yet in its infancy. It was, however, believed that the knowledge of the existence of such laws would act as a check upon the work of those criminal defectives who deliberately adulterate articles intended for the relief of suffering mankind. But such is evidently not the case. In passing it may be remarked that one cannot readily conceive anything more ridiculous and farcical than the hearings on drug adulteration before a police justice.

The following summaries are based upon the personal microscopical examination of crude and powdered vegetable drugs and spices in the Federal Laboratory of San Francisco, the State Laboratory in Berkeley and in the Botanical Laboratories of the California College of Pharmacy. The time covered in this work was from October 1, 1908 to May 1, 1910, or a period of one year and seven months. In all some 1160 samples were examined, grouped as follows:

Group (1) 150 samples of vegetable drugs in the State Laboratory.

  " (2) 350 samples of spices in the State Laboratory.
  " (3) 300 samples of vegetable drugs in the Federal Laboratory.
  " (4) 360 samples of vegetable drugs and spices in the laboratories of the California College of Pharmacy, making the total of 1160 samples.

Group (1) consisted of samples taken from retail pharmacists and wholesale drug dealers in and about San Francisco. The samples of group (2) were taken from the retail and wholesale spice dealers throughout the State of California. In group (3) the samples were secured from well-known Eastern drug importers, and in group (4) the samples were in part taken from retail druggists, some were supplied by wholesale drug dealers and a few samples of spices were obtained from retail grocers and from private families; all in and about San Francisco.

The following are the percentages of adulteration found:

Group (1), percentage of adulterated samples was 38.50.

  " (2),  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  "  

The findings in group (3) are especially interesting as well as surprising and the above figures indicate in a way the terrible condition of affairs that confronts us. The results will serve to emphasize the importance of the work that lies before the committee on drug reform.

California College of Pharmacy, San Francisco, Calif.
SOME OBJECTIONABLE AND UNUSUAL CHINESE DRUGS IMPORTED INTO THE UNITED STATES.

BY ALBERT SCHNEIDER.

1. Introduction.

Many of the ways of the Chinese impress us as being peculiar. This certainly applies to their practice of pharmacy and medicine as has been more fully explained elsewhere.* The quantity and variety of Chinese drugs imported into the United States via San Francisco is very great and is apparently wholly out of proportion to the reasonable needs of the sick of the Chinese population of the United States. It is, however, probable that said drugs are not all used by the Chinese. Within recent years many of the Chinese doctors are making very persistent efforts to extend their practice among Americans, as is evidenced by their extensive advertising in the daily papers and their use of large painted poster ads. in the larger cities of the Pacific Coast, especially in San Francisco and Los Angeles. The special features of their medical advertising are that they use harmless herbs only, cure without the use of the knife and that their superior medication is the result of the accumulated experiences of many centuries. Their American patrons are from the ranks of the uneducated, the easily beguiled, those who are easily humbugged, those who are after something new. Most of the patients are women, although there are also men who visit these Oriental doctors. It may be also stated that the advertising Chinese doctors belong to the better class, judged from the Chinese viewpoint. From the viewpoint of Western scientific medicine they are mere charlatans. It is also a fact that most of the advertising Chinese doctors belong to the old school which is wholly without scientific foundation. Chinese doctors who are graduates of the Western schools of medicine do not advertise, as the universally recognized code of ethics of the regular schools of medicine does not permit it.

The old-school Chinese doctors or herbalists claim to use some three thousand different herbs of tried value, besides many minerals and drugs of animal origin. Some of the latter are very unusual as well as nauseous, and highly objectional for sanitary reasons. This paper will, it is hoped, serve to point out the possible dangers which may lurk in certain Chinese drug imports. It is a fact that the Chinese have no true conception of Western sanitation or of disinfecting and safeguarding against infectious and contagious diseases. The occurrence of small-pox, plague, cholera and other dangerous infectious diseases, is chronic throughout the Chinese empire and every effort should be made to prevent the importation

of articles which may serve as carriers and disseminators of the above-named infections. The publication of the partial list of offensive drugs will, it is hoped, tend to discourage those who show such a decided preference for Chinese doctors and their medicines.

It is further hoped that a fuller knowledge of those articles will bring about a Federal enactment prohibiting the importation of undoubtedly objectionable drug articles.

The list of so-called remedies is given in alphabetical order according to common English names, numbered consecutively for convenience of cross reference. At the close is given an alphabetical list of Chinese names (English equivalents) in the Mandarin dialect, with cross reference to English names by number. This list will prove of value to port inspectors and floor examiners who desire to identify such articles.

It must also be explained that the drugs cited are mostly crude. Thus far it could not be ascertained to what extent these articles, in powdered or other form, occur in compound powders, in pills, in tablets, in plasters, in liquors, in aquae, etc., prepared and prescribed by the Chinese doctors, with increasing experience the writer is less and less willing to make or ganoleptic tests of Chinese pills, powders, tablets, compound teas, etc., submitted for entry at the San Francisco port, because one may never know what particular nauseous ingredients may be present. The writer has also been cautioned by Chinese friends against the promiscuous sampling of drugs, it being declared that some are "very potent."

Some of the packages containing certain of the offensive drugs actually swarm with insect life and absolutely no attempt is made to isolate these packages from those which contain harmless drugs or even food materials that may be included in the same box or bale.

A few of the more offensive Chinese drugs were examined bacteriologically in the laboratory of the U. S. Public Health and Marine Hospital Service, San Francisco, and it was reported that they were sterile as far as pathogenic or otherwise dangerous germs were concerned, excepting the somewhat doubtful finding of a single colon bacillus in one of the articles. Even though the particular samples examined appeared to be harmless, that is absolutely no indication that other samples are also harmless. The following diseases could no doubt be introduced in the following so-called drugs presented for entry at the port of San Francisco:

1. Bubonic plague, in rats' dung and fleas. Whether or not the plague can be imported through these sources is questioned. We can nevertheless ill afford to take chances.

3. Intestinal diseases, including typhoid fever, in human faeces and other similar filth.

4. Skin diseases, in animal hides.

5. Small-pox, in a variety of articles which have been in contact with
individuals having small-pox or just recovering from an attack. Small-pox epidemics occur sporadically throughout the Chinese empire.

Animals, dried and pickled, bones and tissues, animal skins and hides carry various parasites causative of systemic as well as local diseases, unless such articles are thoroughly sterilized or disinfected, which the Chinese certainly do not do as far as can be ascertained.

The following germs of diseases and other causes of disease are always passed in the stools of those suffering from the diseases: typhoid fever, Asiatic cholera, amœbic dysentery, bacillary dysentery, intestinal tuberculosis, bubonic plague, cholera infantum, anthrax, small-pox, measles, scarlet ever and chicken-pox. The larvæ and eggs of tape-worm, pin-worm, hook-worm, etc., occur in the stools. Urine carries pathogenic germs and their spores besides other disease-producers.

With these introductory remarks we shall cite a partial list of the more offensive articles submitted for entry at the port of San Francisco, hoping that the report may influence the members of the American Pharmaceutical Association and induce them to frame resolutions recommending that the importation of offensive, putrid and otherwise objectional drugs be prohibited.

II. ALPHABETICAL LIST OF UNUSUAL OR NAUSEOUS CHINESE DRUGS PRESENTED FOR ENTRY AT THE PORT OF SAN FRANCISCO.

(1) *Alligators' Scales.* Shan kea me.
Used medicinally, but in what manner is not explained. Scales imported in considerable quantity.

(2) *Alligators' Hide.* Shan kea.
Alligators' skin and muscle attached is imported for medicinal use. Cut into strips about ten to fourteen inches long, and dried.

(3) *Armadillo Skin.*
Said to be used medicinally, but just how could not be ascertained. Not seen or not recognized.

(4) *Asses' Glue.* O Keaou. Luh Keaou.
A glue made from the hide of various animals, but especially the ass. To make the glue especially efficacious the animals must have obtained their drinking water from a certain well in the Shantung province, hence the Shantung glue brings the highest price. This glue is essentially a woman's remedy and is used almost solely in diseases of women. Astringent, sedative and tonic properties are ascribed to it.

(5) *Barley Sprouts.* Mei ya.
Used as a stomachic and as food.

(6) *Sprouting Rice.* Kuh ya.
Is similarly used. Given to children to relieve the symptoms of overeating.

(7) *Cow Bezoar.* New hwang.
Concretions found in the gall bladder of the cow. Used as a sedative and tonic, in ulcers, inflammations. External application with camphor. Imported in considerable quantity. Expensive.

(8) Bats' Dung. Way ming sha.
The undigested parts (especially the eyes) of insects eaten by bats, such as fleas and other insects. These particles are carefully picked from the dung. Used as a decoction in the treatment of inflamed eyes. Boil one-half ounce in a cupful of water, strain and drink this amount once daily until cured. Imported.

(9) Beetles. Tang lang.
Resemble the rhinoceros beetle in India. Dried, powdered and used in plasters for sores, ulcers, etc. Not seen in the entire state.

(10) Biche de mer. Hae san.
A marine sea slug or holothurian. Used as food and reputed to have aphrodisiac or tonic properties. Imported. There appears to be considerable confusion as regards the Chinese terms applying to remedies which serve as general tonics and those which have aphrodisiac properties. The general report that the Chinese use aphrodisiacs very extensively is strangely denied by good Chinese authorities who state that this misconception is due to the fact that the Chinese name for “tonic” is often strangely interpreted as “aphrodisiac.”

The dried skin is used externally. Applied to sores, ulcers, etc. Useful in rheumatism. Imported.

(12) Buffalo Horns. Gu kak.
Used to same extent as a medicine in blood troubles. Not seen.

A black beetle of the Scarabaeidae (Coprobius) not unlike our tumble bug. Odor very strong.

Used as a general tonic and in the treatment of genito-urinary diseases.

(15) Cantharides. Red, green and ordinary.
Used for blistering purposes. The red is not a cantharides, it is Heuchys sanguinea (40). Imported.

(16) Centipedes. Woo kung.
These are dried and neatly mounted upon bits of bamboo. The powder is applied externally in venereal diseases, especially to primary and seconded syphilitic sores. Imported in small quantities.

(17) Chamois Horns. Ling yang.
The horns of a small species of antelope found on the plains of Mongolia. Used as a cooling medicine, particularly efficacious in inflammation of the lungs and the liver. The shavings (ling yang peen) are imported. The Chinese consider the tip of the Chamois horn the hardest substance in the world.
1070  MINUTES OF THE SECTION ON SCIENTIFIC PAPERS.

(18) Cicada Shells. Chen Kho.
The cast-off shells of the cicada. A decoction is given to children in indigestion, convulsions, fever, etc. Considered a specific in cataract when given internally. Imported in large quantities.

(19) Cocoons. Sang peaou shaou.

(20) Old Copper Coins. Koo tung tseen.
Boiled in water to obtain the verdigris. Coins are also boiled in vinegar. Made into an ointment. Useful in skin diseases, dysentery, eye diseases, applied to sores, etc. The coin not seen.

A glue made from cowhides, boiled and dissolved in warm water. Used in hemorrhages and in urinary disorders. Much used by the women as a tonic, taken on an empty stomach in the morning. Glues of various kinds are extensively imported.

(22) Cow Sinews. New kin.
Prepared and used like deer sinews. Deer and cow sinews are imported in considerable quantity.

(23) Crickets. Seih suh.
The fighting crickets are used, both male and female. A decoction is given for the purpose of purifying the blood, to cause boils to disappear and to hasten suppuration. Imported.

(24) Cuttlefish Bones. Woo tseh küh.
The calcareous substance commonly known as cuttlefish bones is boiled. Said to have cooling properties; used in gonorrhoea as a vermifuge, in ulcers, boils, sores, burns; in diseases of the eye, hemorrhage, etc. Imported.

(26) Deer Sinews. Lūh kin.
Said to be boiled with eggs, shrimps and other food substances, taken by invalids as a great restorative tonic. Imported.

(27) Dragons' Bones. Lung kūh.
Fossil ivory, occurring in irregular pieces, weighing perhaps a few ounces. Ground to a fine powder, used in fever and ague, chorea and spermatorrhoea.

Various substances are comprised under this name as the fossil teeth of *Stegodon stinisens* and of *S. orientalis* (extinct elephants), horns of *Cali- otherium sinense*, the teeth of *Hyla sinensis*, the molars of mastodons, elephants, sheep, teeth of hippotherium and perhaps of other animals, modern and extinct. Reduced to a powder and used as a restorative tonic, as a sedative or cordial. Imported.

(30) *Earth Worms*. Keuh shen.
Used as a vermifuge, in colds and fevers, to relieve retention of urine; externally in the treatment of bites, sores, ulcers in ear, eye and mouth troubles.

(31) *Eel's Blood*. Shen yu heuè.
The eels are placed alive in cold water and gradually brought to the boiling temperature. They are then taken out and the long intestine containing the blood is removed and dried. Used in sunstroke. If applied to the side of the face not affected it is said to give instant relief and cause the face to assume its normal appearance. The fresh eels' blood is more efficacious than the dried. Also used in ringworm, and in mouth, ear, eye and nose treatment. Not recognized.

The egg skin taken immediately after the chicken is hatched. This is dried, powdered and mixed with safflower, ginseng, and dates and given in jaundice. Imported.

(33) *Eggs of Silkworm*. Tsan tsz.
The dried eggs of the silkworm are used in the treatment of smallpox. Not seen.

Used as an application to fresh cuts and wounds. Also used as a tonic. Only the shredded hide was seen (Cheow pvay). Imported.

Dried, in irregular pieces, cut into uneven cubes and formed into cakes the size of small ginger snaps. Apparently unprepared and unmixed with anything else, the natural odor being very pronounced in the samples thus far found. Samples examined bacteriologically in the laboratory of the U. S. Marine Hospital Service, San Francisco, gave negative results. Said to be useful for bites, burns, ulcers and to counteract poisons; useful in hemorrhages, fevers, dyspepsia, etc. Imported.

Equal parts of human excrement, licorice, bran and other ingredients mixed, decocted and rammed into hollow bamboo stems and the ends hermetically sealed; then boiled for a long time. According to some no human excrement is added, but the mass in the bamboo is placed in the privy for a time, soaked in the mixture of faeces and urine; then removed, dried and boiled, as above.

(37) *Fish Glue*. Ye keaou.
Used medicinally and for gluing purposes. Imported.
(38) Fish Stomachs. Fish Bellies. Yu tu.
The dried lower belly of several species of large fish, eaten and used
as a tonic medicine. Not seen (?)
(39) Black Flies.
Glossy black flies, somewhat larger than a bumble bee, resembling a
wasp. Use not determined. Imported.
Not a blistering beetle. Properties and uses not ascertained. Im-
ported.
(41) Pickled Domestic Fowl.
Plucked, and prepared in some kind of brine. Odor bad, recalling the
dissecting room.
Made from frogs and considered very useful in the treatment of catarrh,
in intestinal troubles, worms, etc.; as a diuretic, sedative, etc. Not seen.
(43) Dried Frogs. Tin gi.
Dried frogs (single, not in pairs) on bamboo frames are imported.
Use not determined.
(44) Burnt Ginger. Keung hon.
Common ginger burnt until almost wholly charred. Given as a last
resort in fatal sickness. (Dr. Leung.) Imported in considerable quan-
tity.
(45) Gizzard Membrane. Ke chun pe.
The lining membrane of the gizzard of the domestic fowl peeled off and
dried. The membrane from the male fowl is used for female patients and
vice versa. Used in dyspepsia, diarrhoea, spermatorrhœa and in urinary
complaints. Practically identical with the Pelliulœ stomachi gallioi interi-
ores of the London Pharmacopœia (1721) and similar to the Ingluvin of
modern materia medica. Not seen.
(46) Hedgehogs’ Skin. Tsze wei pe.
The dried skin of the common hedgehog. The decoction is taken in
pulmonary complaints. The powder in pills is taken for skin diseases.
May carry skin diseases. Imported.
Used as a cordial and tonic and as a pigment. Imported.
(48) Parasitized Insect Larvae. Tung Chung hae tsaoou.
A peculiar nature. freak. The larvæ of the insects are attacked by a
fungus and gradually killed. Finally the entire substance of the larva is
replaced by the mould tissue, retaining the exact form of the larva. A
spore-bearing stipe develops from the head of what was originally the in-
sect. Some years ago this freak excited considerable curiosity among
botanists. Also obtained from Australia. Use not determined. Imported
in considerable quantity.
(49) *Insect Skins.* Chen tuy.
Used medicinally. Imported.

(50) *Ivory Shavings.* Seang ya seao.
Decocted. Cooling and tonic. Given to weakly children who have a tendency to spinal troubles. Not seen.

(51) *Lizards.* Peih hoo.
The common spotted house lizards of China. Dried, powdered and used as an ingredient in plasters for sores, ulcers, wounds, etc. They are very extensively imported, neatly dried over a bamboo frame, always in pairs, male and female. The Chinese have great faith in the proper combination of the male and female principle (the *yang* and the *yin*). A tea is made by dipping the lizards in boiling water. The pair of lizards is thus used over and over. Tonic.

(52) *Dried Leeches.* Shwuy chih.
Made into a decoction when required, either in water or Chinese gin or brandy and taken internally as a purgative. Also applied externally to bruises.

(53) *Leek or Garlic Seeds.* Kew tsae tsze.
Boiled in spirits and taken internally for rheumatism, neuralgia and other pains. Imported.

(54) *Maggots.* Woo kub chung.
Collected from water closets, dried and powdered. A decoction is given to children suffering from over-eating. Acts as a mild purgative. A filthy substance the use of which is wholly foreign to the modern conception of sanitation. Not discovered.

(55) *Manis Scales.* Chuen shan kea.
Decocted and given in venereal diseases. Not seen (?).

Said to be very efficacious in the treatment of hydrophobia. Imported.

(57) *Rabbits' Dung.* Wany yue sha.
A decoction is used in the treatment of asthma. Imported.

(58) *Rats' Dung.* Leang tow tseen.
Dried and powdered. Applied to sores and ulcers.

(59) *Rhinoceros Hide.* Se pe. Sai pe.
Boiled into a jelly and given as a tonic. Imported.

(60) *Rhinoceros Horns.* Se keo. Sai kok.
Used as a strengthening tonic and as an antidote to poisons. Considered of great value. Also used as cups, cornucopias, etc. Flamed or shaved up very fine and made into a decoction. Taken in small quantities. Imported.

(61) *Rhinoceros Horn Shavings.* Se keo peen.
Decocted or boiled to a jelly. Cooling and strengthening. Given to women in child-birth. Not seen.

(62) *Scorpions.* Chuan hee.
A variety of true scorpion, about two inches in length, dried and usually heavily salted. Coolies eat them raw and alive. Considered of great value as a diaphoretic in fevers and serious diseases. Given to teething children. Imported.

(63) Scouring Rush. Muh tsee tsaou.
A decoction is taken internally for weak and sore eyes. Imported.

(64) Sea Horse. Hae ma.
A decoction is used in female disorders. Said to be strengthening. Imported.

(65) Black Shark's Fins. He yu chih.
Used as food and as a tonic stimulant. Imported.

Used as food and as a tonic stimulant. Imported in large quantities.

(67) Sheep's Entrails. Yang chang.
The intestines of the sheep used in the manufacture of bowstrings; also used medicinally. Not seen.

(68) Shells. Wa lang tsze (cockle shells) Han lo kho (Snail sheels), Ho le kho (clam shells), Mow le kho (oyster shells).
Broken and decocted; also powdered. An ingredient in plasters for sores and ulcers. Imported.

(69) Dried Silk Worms. Tsan chung and other names.
The larvae of the silk moth, powdered and decocted, given to children for colds, fevers, etc. An infusion is used as an eye wash. Imported.

(70) Silk Worm Pupa. Keang tsan.
Used medicinally, but just how was not explained.

(71) Green Snakes. Taing seau shay.
Small green snakes made into a decoction, taken twice daily, in the treatment of skin eruptions, blotchy skin, etc. Not seen.

(72) Snakes' Skin. Dragon's skin. Shay pe.
Skins shed by snakes. Thoroughly boiled and taken in gonorrhoea. Imported in considerable quantities.

Not supposed to be effective unless found standing in upright position on the ground. The decoction is taken to purify the blood and to hasten the suppuration of boils. A poultice made with pepper and wine is applied to sores and wounds. Not seen.

(74) Spiders. Che choo.
Eaten whole or beaten up in water, taken three times daily to relieve flatulence. Not seen.

(75) Tiger's Bone. Wine. Tsaou Hoo Kuh.

(76) Tiger's Bones. Hoo kuh.
The bones of the tiger, Leopardus brachyurus. Reduced to a powder
mixed with hartshorn and plastron of tortoise, forming a tonic jelly used in rheumatism and diseases of the bones and joints, in ague and in general debility. A strengthening remedy in great repute among the Chinese. Never given to women as it is supposed to cause difficulty in childbirth. Bones of various animals imported in considerable quantity.

(77) Toads. Lae twan.

The toads are dried and made into a decoction which is taken internally in the treatment of elephantiasis and leprosy. Applied as an ointment or plaster to sores, ulcers, etc. The toads are also boiled alive in spirits, the liquor thus prepared being more active than the decoction made from the dried toads. Not seen.

(78) Toad Cakes. Chen soo.

The living toad is placed in a jar and poked with a stick; the enraged animal secretes a slimy substance which is wiped off, mixed with flour, made into cakes and dried. Also appears in powdered form. Another preparation is made by scraping the mucus from the warts of the living toad, mixing with flour, etc., as above. Taken as snuff. Very efficacious to restore in fainting and in fits. Not recognized.

(79) Tortoise Shell. Kwei pan.

The carapace and plastron of several species of tortoise and turtle are used medicinally. The shells are sometimes partially roasted. Imported in considerable quantity.

(80) Turtle's Head. Kea yu tow.

The heads of the common fresh-water turtles are dried and powdered and applied to sores and ulcers. Not recognized in powders. Heads not seen thus far.

This is the "fur" (a nasty mixture of urine, mould, bacteria, etc.), which collects in urinals after a time, when not cleaned. Decocted with ginseng and other vegetable substances. Boys' urine, not girls, is used. Said to neutralize the stimulating effects of ginseng and other strengthening medicines, possesses demulcent properties, used in lung troubles, to cure debility, as an eye lotion. Eggs boiled in boys' urine are considered very strengthening, eaten by the old and decrepit of both sexes. A favorite medicine. Not recognized thus far.

(82) Horned Viper.

The entire snake, with entrails removed, dried on a bamboo frame. Use not determined. Imported in considerable numbers.

(83) Wasps' Nests. Foo fung kho.

Made into a decoction and given in consumption. Imported in considerable quantity.

(83) Wasps' Nests. Fung fang.

Used medicinally, just how is not clear. Imported in considerable quantity.
(84) Earth Worms. Earth dragon. Kheuh shan.
Made into a decoction and taken in cases of gonorrhoea.
Perhaps not imported, unless in powdered form, mixed with other things. Not recognized.

III. CHINESE NAMES OF THE ARTICLES MENTIONED, WITH NUMBER CROSS REFERENCE TO ENGLISH NAMES AND DESCRIPTIONS.

VOLUMETRIC CALCULATIONS OF THE U. S. P.

BY FRANK X. MOERK.

In a paper presented at the 1908 meeting, a classification of official quantitative determinations was given and attention called to the varied methods of procedure; this was followed in 1909 by a second paper containing a classification in which those substances were grouped together for which like processes could be formulated. The present paper takes up the calculations in official volumetric processes and shows that here again varied methods are given which, however, can readily be systematized. The processes may be grouped as Direct and as Residual or Indirect Titrations. In Direct Titrations one volumetric solution is used either with or without accessory reagents, the latter acting upon the substance to be determined but having no action upon the volumetric solution, as in use of glycerin in $H_3BO_3$ determination, KI in Ferric salts, NaCl in $H_3PO_4$, etc.

In Residual Titrations there may be used:

(1) a V. S. in excess acting upon the substance to be determined and the excess determined by means of a second V. S., or,

(2) a reagent not employed as the V. S. which acts upon the substance to be determined, liberating quantitatively a product which is then determined by means of a V. S., as in the use of $Na_2SO_4$ in the estimation of aldehydes. A Blank Test is essential in residual titration and should be made under identical conditions (but omitting the substance to be determined) so as to establish the relation between the two V. S. or the reagent and the V. S.; the difference between the two titrations gives the Cc. V. S. corresponding to the substance to be determined. In the case of alkaloidal assays the alkaline V. S. should be standardized using the indicator designated in the assay process.

Generally the Blank Test will require the greater volume of the V. S., but the reverse is sometimes true as in aldehydic determinations.

When two V. S. are used the calculation can be based upon either, giving in one case the Cc. V. S. which actually reacts with the substance to be determined, in the other case giving the Cc. V. S. which is equivalent to the substance to be determined: in using standard V. S. it makes no difference if we figure to the same strength solutions (as is done in the alkaloidal assays and in Reduced Iron) but in using empirical V. S. it is always simpler to calculate from the last V. S. which is used (as in case of alkaloidal assays upon the alkaline V. S., in Phenol and Iodine figures

California College of Pharmacy, San Francisco.
Na₂S₂O₃ V. S., Goulard's solution upon K₂Mn₂O₈, V. S., saponification-figures upon HCl V. S., etc.

To save space and avoid unnecessary repetitions the following letters are used:

A = Cc. V. S. in a Direct Titration, or Cc. gas evolved in a gasometric determination.

B = Cc. V. S. in a Blank Test.

C = Cc. of last V. S. in a Residual Titration.

W = Weight taken (or Cc. taken in case of Alkaloidal Fluidextracts and Tinctures, H₂O₂, Ca(OH)₂, Lemon Juice, Tincture of Iodine).

A complete mathematical statement is given to show how certain factors used in the U. S. P. are obtained; this is followed by a statement in which the factor is used and lastly, if a discrepancy exists between the calculated and the U. S. P. factor or percentage, the latter is given in parenthesis.

I. Factors given for calculations:

A. Yielding weight found

NH₃ Spirit \[
\frac{2 \times 16.93 \times 0.0243375 \times A \times 100}{97.35} \text{ or } \frac{0.008465 \times A \times 100}{(W \ 2 \ Cc.)}
\]

Benzaldehyde and Oil B. Almond \[
\frac{105.25 \times 0.01809 \times (C-B) \times 100}{36.18} \text{ or } \frac{0.052625 \times (C-B) \times 100}{(W \ 12 \ drops)}
\]

Cinnaldehyde \[
\frac{131.07 \times 0.01809 \times (C-B) \times 100}{2 \times 36.18} \text{ or } \frac{0.03277 \times (C-B) \times 100}{(W \ 12 \ drops)}\]

Citral (Oil Lemon) \[
\frac{150.98 \times 0.01809 \times (C-B) \times 100}{2 \times 36.18} \text{ or } \frac{0.037745 \times 100}{(W \ 15 \ Cc.)}
\]

B. Yielding percentage found

HA Glacial \[
\frac{59.58 \times 0.05574 \times A \times 100}{55.74} \text{ or } \frac{5.958 \times A}{(W \ 3 \ Cc.)}
\]

HC1 \[
\frac{36.18 \times 0.05574 \times A \times 100}{55.74} \text{ or } \frac{3.618 \times A}{(W \ 3 \ Cc.)}
\]

HNO₃ \[
\frac{62.57 \times 0.05574 \times A \times 100}{55.74} \text{ or } \frac{6.257 \times A}{(W \ 3 \ Cc.)}
\]

H₂SO₄ \[
\frac{97.35 \times 0.05574 \times A \times 100}{2 \times 55.74} \text{ or } \frac{4.8675 \times A}{(W \ 3 \ Cc.)}
\]

NH₃ Water \[
\frac{2 \times 16.93 \times 0.048675 \times A \times 100}{97.35} \text{ or } \frac{1.693 \times A}{(W \ 3 \ Cc.)}
\]

NH₃ Water Strg'r \[
\frac{97.35}{246.46} \text{ or } \frac{1.259 \times A}{(W \ 0.5 \ Gm.)}
\]

KOH \[
\frac{2 \times 55.74 \times 0.048675 \times A \times 100}{97.35} \text{ or } \frac{5.574 \times A}{(W \ 1 \ Gm.?)}
\]

NaOH \[
\frac{2 \times 39.76 \times 0.048675 \times A \times 100}{97.35} \text{ or } \frac{3.976 \times A}{(W \ 1 \ Gm.?)}
\]

I \[
\frac{125.9 \times 0.024646 \times A \times 100}{(W \ 0.5 \ Gm.)} \text{ or } \frac{1.259 \times A}{(W \ 0.5 \ Gm.)}
\]
VOLUMETRIC CALCULATIONS OF THE U. S. P.

C₈H₁₁NO₂

\[
0.000089876 \times 29.81 \times 116.24 \times 273 \times \text{Bar. pres. (760) \times A} \times 100 \times \text{Cc. made \times 100}
\]

\[
2 \times 29.81 \times (273 + 25^\circ) \times 760 \times \text{100 Cc. used \times (W 3 Cc.)}
\]

or \[4.7854 \times A \quad (4.8)\]

(W 3 Cc.)

C₂H₅NO₂ spirit

\[
0.000089876 \times 29.81 \times 74.51 \times 273 \times \text{Bar. Pres. (760) \times A \times 100 Cc. made \times 100}
\]

\[
2 \times 29.81 \times (273 + 25^\circ) \times 760 \times \text{10 Cc. used \times (W 3 Cc.)}
\]

or \[0.30674 \times A \quad (0.307)\]

(W 30 Cc. + 10)

Cl in CaCl₂

\[
35.18 \times 0.024646 \times A \times 100 \quad \text{or} \quad 0.3518 \times A
\]

246.46 \quad \text{(W 3-4 Gm. + 10)} \quad \text{or} \quad \text{(W 3-4 Gm. + 10)}

SO₂ in H₂SO₃

\[
63.59 \times 0.024646 \times (B-C) \times 100 \quad \text{or} \quad 0.31795 \times (B-C) \quad (0.318)
\]

2 \times 246.46 \quad \text{(W 2 Cc.)} \quad \text{or} \quad \text{(W 2 Cc.)}

HCOH

\[
2 \times 29.79 \times 0.048675 \times (B-C) \times 100 \quad \text{or} \quad 2.979 \times (B-C)
\]

97.35 \quad \text{(W 3 Cc.)} \quad \text{or} \quad \text{(W 3 Cc.)}

C₁₀H₁₉C₂H₅O₂

(\text{in Oil Peppermint})

\[
2 \times 196.68 \times 0.0243375 \times (B-C) \times 100 \quad \text{or} \quad 9.834 \times (B-C)
\]

97.35 \quad \text{(W 10 Cc.)} \quad \text{or} \quad \text{(W 10 Cc.)}

C₁₀H₁₇C₂H₅O₂

(\text{in Oil Rosemary})

\[
2 \times 194.68 \times 0.0243375 \times (B-C) \times 100 \quad \text{or} \quad 9.734 \times (B-C)
\]

97.35 \quad \text{(W 10 Cc.)} \quad \text{or} \quad \text{(W 10 Cc.)}

Iodine figures

\[
125.9 \times 0.024646 \times (B-C) \times 100 \quad \text{or} \quad 1.259 \times (B-C)
\]

246.46 \quad \text{(W 0.15-0.3 Gm.)} \quad \text{or} \quad \text{(W 0.15-0.3 Gm.)}

Alkaloidal Assays.

Aconite

\[
2 \times 640.55 \times 0.0048675
\]

97.35

\[
0.064055 \times \left(\frac{\text{Cc. N/10 H}_2\text{SO}_4}{5} - \frac{\text{Cc. N/50 KOH}}{5}\right) \times 100 \quad \text{W} \quad (0.064)
\]

Mydriatic Drugs

\[
2 \times 287.04 \times 0.0048675
\]

97.35

\[
0.028704 \times \left(\frac{\text{Cc. N/10 H}_2\text{SO}_4}{5} - \frac{\text{Cc. N/50 KOH}}{5}\right) \times 100 \quad \text{W} \quad (0.0287)
\]

Coca

\[
2 \times 300.02 \times 0.0048675
\]

97.35

\[
0.030092 \times \left(\frac{\text{Cc. N/10 H}_2\text{SO}_4}{5} - \frac{\text{Cc. N/50 KOH}}{5}\right) \times 100 \quad \text{W} \quad (0.03)
\]

Nux Vomica

\[
2 \times 331.73 \times 0.0048675
\]

97.35

\[
0.033173 \times \left(\frac{\text{Cc. N/10 H}_2\text{SO}_4}{5} - \frac{\text{Cc. N/50 KOH}}{5}\right) \times 100 \quad \text{W} \quad (0.0332)
\]

Ipecac

\[
(231.43+245.34) \times 0.0048675
\]

97.35

\[
0.0238385 \times \left(\frac{\text{Cc. N/10 H}_2\text{SO}_4}{5} - \frac{\text{Cc. N/50 KOH}}{5}\right) \times 100 \quad \text{W} \quad (0.0238)
\]

Physostigma

\[
2 \times 273.2 \times 0.0048675
\]

97.35

\[
0.02732 \times \left(\frac{\text{Cc. N/10 H}_2\text{SO}_4}{5} - \frac{\text{Cc. N/50 KOH}}{5}\right) \times 100 \quad \text{W} \quad (0.0273)
\]
Pilocarpus

\[
2 \times 206.63 \times 0.0048675 = 97.35
\]

\[
0.020663 \times \left( \frac{\text{Cc. N/10 H}_2\text{SO}_4}{\text{Cc. N/50 KOH}} \right) \times 100 \quad \left(0.02\right)
\]

These calculations may be made as follows using as illustration

\[
640.55 \times \text{KOH in 1 Cc. V. S.} \times (B-C) \times 100
\]

\[
\text{W} = \text{Total Alcohols in Essential Oils.} \quad (W = \text{weight of Acetylated Oil taken})
\]

Menthol in Oil of Peppermint.

\[
2 \times 196.68 \times 154.98 \times 0.00243375 \times (B-C) \times 100
\]

or

\[
97.35 \times 196.68 \times [0.02085 \times (B-C)]
\]

or

\[
7.749 \times (B-C) \quad \left(0.021\right)
\]

\[
\text{W} - [0.02085 \times (B-C)]
\]

\[
\text{W} = \text{Borneol in Oil of Rosemary.}
\]

\[
2 \times 152.98 \times 0.0243375 \times (B-C) \times 100
\]

or

\[
11.0265 \times (B-C) \quad \left(11.026\right)
\]

\[
\text{W} - [0.02085 \times (B-C)]
\]

C. Factors giving parts of Reagent per 1000 parts of Substance (or Mgm. KOH per 1 Gm. substance).

1. Acid figures in Guaiac, Mastic, Rosin.

\[
0.02787 \times A \times 1000 \quad \text{or} \quad 27.87 \times A \quad \text{W(1 Gm.?)} \quad \text{W(1 Gm.?)}
\]

2. Saponification figures in Wax, Fixed Oils and Oil of Rose.

\[
55.74 \times 0.01809 \times (B-C) \times 1000 \quad \text{or} \quad 27.87 \times (B-C)
\]

\[
36.18 \quad \text{W(1.5-2 Gm.?)} \quad \text{W(1.5-2 Gm.?)}
\]

II. Every Cc. V. S. required is equal to a definite per cent. purity; depend upon the weight taken for titration being simply related to the molecular weight of the substance desired in the assay; several methods, it will be seen, are used to obtain this weight.

A. 1 Cc. V. S. = 5%.

\[
\text{H}_3\text{PO}_4 \quad 97.29 \times 0.05574 \times 17 \times 100 \times \text{Cc. made} \times 100 = 84.991\% \quad (85)
\]

\[
2 \times 55.74
\]

\[
\text{K}_2\text{SbOC}_4\text{H}_4\text{O}_6 \quad 659.8 \times 0.07259 \times 19.9 \times 100 \times \text{Cc. made} \times 100 = 99.47\% \quad (99.5)
\]

\[
4 \times 125.9
\]

\[
40.06 \times 0.05574 \times (25 \times 5.8 \times \text{Cc.}) \times 100
\]

\[
2 \times 55.74 \quad 0.4 \text{ Gm.} = 96.144\% \quad (96)
\]

MgO and MgCO_3 U. S. P. (after ignition)
### B.

1. **CC. V. S. = 4.04%.**

\[
\text{ZnO} \quad \frac{80.78 \times 0.05574 \times (30 \text{ Cc.} - 5.5 \text{ Cc.}) \times 100}{2 \times 55.74} \quad \text{1 Gm. (after ignition)} = 98.955\% (99)
\]

### C.

1. **CC. V. S. = 4%.**

\[
\text{H}_2\text{C}_6\text{H}_5\text{O}_2\text{H}_2\text{O} \quad 208.5 \times 0.05574 \times 24.87 \text{ Cc.} \times 100 \text{ Cc. made} \times 100 \quad 3 \times 55.74 \quad 34.75 \text{ Cc. used} \times 5 \text{ Gm.} = 99.48\% (99.5)
\]

\[
\text{CrO}_2 \quad 99.34 \times 0.024646 \times 22.5 \text{ Cc.} \times 100 \text{ Cc. made} \times 100 \quad 3 \times 246.46 \quad \frac{8.3 (8.28) \text{ Cc. used} \times 1 \text{ Gm.}}{55.74} = 89.77\% (89.98)
\]

\[

Acid Figures.

Balsam Copaiba \( \frac{0.02787 \times 2.3 \text{ Cc. to } 3.2 \text{ Cc.} \times 1000}{1 \text{ Gm.}} = 64.1 \text{ to } 89.18 \).

Balsam Peru \( \frac{0.02787 \times 2 \text{ Cc.} \times 1000}{1 \text{ Gm.}} = 55.74 \).

Balsam Tolu \( \frac{0.02787 \times 4 \text{ Cc. to } 6 \text{ Cc.} \times 1000}{1 \text{ Gm.}} = 111.48 \text{ to } 167.22 \).

Resin Jalap \( \frac{0.02787 \times 0.5 \text{ Cc.} \times 1000}{1 \text{ Gm.}} = 13.93 \).

Lard \( \frac{0.05574 \times 0.2 \text{ Cc.} \times 1000}{10 \text{ Gm.}} = 1.115 \).

Wool-fat \( \frac{0.05574 \times 0.05 \text{ Cc.} \times 1000}{2 \text{ Gm.}} = 1.393 \).

Saponification figures.

Balsam Tolu \( \frac{0.02787 \times [20 \text{ Cc.} - (13.2 \text{ Cc. to } 14.5 \text{ Cc.})] \times 1000}{1 \text{ Gm.}} = 189.52 \text{ to } 153.28 \).

Resin Jalap \( \frac{0.02787 \times (25 \text{ Cc.} - 20 \text{ Cc.}) \times 1000}{1 \text{ Gm.}} = 139.35 \).

Ester figure.

Balsam Peru \( \frac{0.02787 \times (25 \text{ Cc.} - 1.32 \text{ Cc.}) \times 1000}{1 \text{ Gm.}} = 131.55 \).

Allowable Acidity. These in many cases can be calculated or expressed in percentage of some definite substance of acid reaction.

HCOH Solution \( \frac{45.67 \times 0.05574 \times 1 \text{ Cc.} \times 100}{20 \text{ Cc.} \times 1.076} = 0.21 \% \text{ HCHO}_2 \).

\((\text{C}_2\text{H}_5\text{OH})_3\) \( \frac{59.58 \times 0.05574 \times 0.5 \text{ Cc.} \times 100}{55.74 \times 8 \text{ Cc.} \times 0.99} = 0.38 \% \text{ HC}_2\text{H}_3\text{O}_2 \).

Malt \( \frac{89.37 \times 0.005574 \times 3.35 \text{ Cc.} \times 100}{10 \text{ Gms.}} = 0.3 \% \text{ HC}_3\text{H}_5\text{O}_3 \).

Wine Red \( \frac{148.92 \times 0.05574 \times 4 \text{ (to } 5.1 \text{ Cc.}) \times 100}{2 \times 55.74 \times 50 \text{ Cc.}} = 0.45 \text{ to } 0.77 \% \text{ H}_2\text{C}_4\text{H}_6\text{O}_6 \).

Wine White \( \frac{13.35 \times 0.05574 \times 4 \text{ (to } 5.1 \text{ Cc.}) \times 100}{2 \times 55.74 \times 50 \text{ Cc.}} = 0.45 \text{ to } 0.77 \% \text{ H}_2\text{C}_4\text{H}_6\text{O}_6 \).

Whisky \( \frac{59.58 \times 0.05574 \times 1.2 \text{ Cc.} \times 100}{55.74 \times 100 \text{ Cc.}} = 0.071 \% \text{ HC}_2\text{H}_3\text{O}_2 \).

Brandy \( \frac{59.58 \times 0.05574 \times 1 \text{ Cc.} \times 100}{55.74 \times 100 \text{ Cc.}} = 0.06 \% \text{ HC}_2\text{H}_3\text{O}_2 \).

Allowable Acidity. In cases not included in the above could be expressed as Acid figures.

\(\text{C}_5\text{H}_{11}\text{NO}_2 \frac{0.05574 \times 0.05 \text{ Cc.} \times 1000}{5 \text{ Cc.} \times 0.87} = 0.64 \).

\(\text{Ca(H}_2\text{PO}_4)_2 \frac{0.005574 \times 1 \text{ Cc.} \times 1000}{1 \text{ Gm.}} = 5.57 \).

\(\text{H}_2\text{O}_2 \text{ Solution } \frac{0.005574 \times (5 \text{ Cc.} - 2.5 \text{ Cc.}) \times 1000}{25 \text{ Cc.}} = 0.56 \).

Allowable Alkalinity. These in most cases can be calculated or expressed as corresponding carbonates; in a few cases as hydroxides.
VOLUMETRIC CALCULATIONS OF THE U. S. P. 1087

\[
\begin{align*}
\text{KBr} & \quad 137.27 \times 0.0048675 \times 0.1 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 0.07 \% \text{ K}_2\text{CO}_3 \\
\text{KI} & \quad 97.35 \times 0.0048675 \times 0.1 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 0.07 \% \text{ K}_2\text{CO}_3 \\
\text{K(H}_2\text{PO}_4) & \quad 137.27 \times 0.003618 \times 1.5 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 1.03 \% \text{ K}_2\text{CO}_3 \\
\text{Na(H}_2\text{PO}_4) & \quad 105.31 \times 0.003618 \times 1.5 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 0.79 \% \text{ Na}_2\text{CO}_3 \\
\text{NaBr} & \quad 105.31 \times 0.0048675 \times 0.1 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 0.053 \% \text{ Na}_2\text{CO}_3 \\
\text{NaI} & \quad 97.35 \times 0.0048675 \times 0.1 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 0.053 \% \text{ Na}_2\text{CO}_3 \\
\text{NaHCO}_3 & \quad 105.31 \times 0.03618 \times 0.2 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 2.11 \% \text{ Na}_2\text{CO}_3 \\
\text{Soap} & \quad 2 \times 39.76 \times 0.006255 \times 3 \text{ Cc.} \times \frac{100}{5 \text{ Gm.}} = 0.24 \% \text{ NaOH} \\
\text{Soap Soft} & \quad 2 \times 55.74 \times 0.006255 \times 2.3 \text{ (to 4.5) Cc.} \times \frac{100}{125.1} \text{ Gm.} = 0.26 \text{ to} 0.50 \% \text{ KOH} \\
\text{ZnCO}_3 & \quad 105.31 \times 0.003618 \times 1 \text{ Cc.} \times \frac{100}{1 \text{ Gm.}} = 0.53 \% \text{ Na}_2\text{CO}_3
\end{align*}
\]

The following suggestions are made to bring about uniformity in processes and calculations and to make them more practical so as to correspond better with the methods of the analyst:

(1) That a definite volume of a liquid be taken, either as Cc. or drops, and accurately weighed, as directed now in the assay of strong mineral acids, formaldehyde, benzaldehyde, etc., etc.

(2) That approximate weights of solids be accurately determined as is now the case with KOH, NaOH, etc., etc.

(3) That instead of giving results in Cc. V. S., these be expressed either in per cent. of the substance to be determined or given as acidity, saponification or ester figure.

(4) That where an abbreviated calculation involves a factor the latter be in accordance with (3).

(5) That the common fractions used in the correction for temperature and barometric pressure in gasometric determinations be replaced by decimal fractions.

(6) In those cases where the percentage results are apt to run above 100 as in the case of haloid salts, a statement could be given why this is allowable or else a short method given by which the actual content of the important constituent can be determined as by a differential calculation; in gravimetric processes the same condition exists in the lithium salts.

By following these suggestions the weight used in a determination can be rapidly obtained, avoiding the danger of concentration by evaporation or diminished weight of active material by absorption of moisture. In looking over the statements for calculations it will be seen that frequently two weights or volumes are given, the first of the two as a rule yields a deficient percentage of purity and to obtain the official percentage the
second figures are necessary; thus (1) under dilute HNO₃ 6.26 Gm. (6.257 Gm.) are directed to be taken; (2) under Goulard's extract 13.6 Cc. (13.594 Cc.) of a dilution are to be taken; and (3) under sodium salicylate 12.5 Cc. (12.52 Cc.) of the V. S. are stated to be necessary. Whilst only single illustrations are here given, inspection of the statements will reveal many others.

In conclusion the writer wishes to state again that this series of papers upon the quantitative tests was written for the purpose of bringing about greater uniformity, and trusts that the papers will be of assistance to the next revision committee.
MINUTES
OF THE
SECTION ON PRACTICAL PHARMACY AND DISPENSING.

FIRST SESSION—FRIDAY AFTERNOON, MAY 6, 1910.

The first session of the Section on Practical Pharmacy and Dispensing was called to order by Chairman Otto Raubenheimer, of Brooklyn, at 3:30 p. m., and Mr. Raubenheimer asked his Associate on the Committee, Mr. White, to preside while he read his Address as Chairman:

Fellow Members: First of all permit me to thank you for electing me Chairman of the Section on Practical Pharmacy and Dispensing at the Los Angeles Meeting, although I was prevented from being present. I greatly appreciate the honor and as I have devoted a good deal of my time to the interest of this Section as well as the Association in general, I thereby hope I have "made good."

I congratulate the A. Ph. A. on the improved outlook in Pharmacy and quite especially in Practical Pharmacy and Dispensing. It must be remembered that Pharmacy is no longer in its infancy; it has even passed its youth and is now in its full manhood in the U. S. The present age is said to be one of commercialism, and we are accustomed to portray Americans as exclusively occupied with business affairs, having as their mottos, "Time is money" and "Business is business."

But we stand on the threshold of a new century, a century of science, a century in which science and business can be combined, a century in which practical pharmacy and dispensing can be thoroughly developed and practiced.* Just about a hundred years ago the world gave birth to such eminent chemists as Woehler, Liebig, Graham, Boettger, Laurent, Regnault, Péligot, and Bunsen, to such eminent pharmacists as Mohr, Boullay, Redwood, Pelouze, Otto, Landerer, Wittstein, Monsel and Fehling, and also to such eminent botanists, pharmacognosists, pharmacologists as Wiggers, Basham, Schwann, Darwin, de Vrij, Berg, Mueller, etc. What a collection of immortal names! We will soon celebrate the centennial of the discovery of the most important alkaloids, the centennial of the birth of our U. S. P. and the centennial of the foundation of the oldest college of pharmacy in the U. S. Let us hope that this coming decade will be equally as productive and will be one that will be remembered in the annals of pharmacy.

* Standing as we do, on this historic ground of Virginia, I cannot pass on without mentioning a few historical pharmaceutic data.

69 (1089)
During the past few years, Pharmacy, the daughter of Galenus, and Medicine, the daughter of Hippocrates, have been aroused from their sleep and indolence by various causes. The Pure Food and Drugs Act which compelled the manufacturers to tell the truth on the label, the American Medical Association which exposed the Nostrums, the U. S. P. and N. F. propaganda which so successfully sweeps the entire country, and, last but not least, the A. Ph. A. with their grand work and the establishment of the various branches, all have done their share to greatly benefit practical pharmacy and dispensing. Joint meetings are being held all over the U. S. with the intention of getting physicians and pharmacists into closer touch, and with the intention of getting physicians to prescribe official U. S. P. and N. F. preparations instead of proprietary and nostrums.

At one of these meetings in New York City, quite a novel feature was brought out by Dr. Bastedo of the College of Physicians and Surgeons, namely, the establishment of "certified" pharmacies: Just as the purest milk is distinguished from the ordinary kind by being certified, the doctor recommends to separate the "sheep from the goats" in pharmacy by the establishment of certified pharmacies.

In my opinion this is an excellent idea and ought to be further followed up. In France practically, the same condition exists by having pharmacists of the first and second class. A member of the A. Ph. A., especially one who attends the meetings, contributes papers and takes part in the discussions, can in my opinion be justly called a "certified" pharmacist. I would therefore advise the better class of druggists and pharmacists to join the A. Ph. A. and display their certificates of membership as being the equal of a diploma of "certified" pharmacist. The time will surely come when there will be two classes of pharmacists, perhaps classed as druggists and pharmacists as for instance in Germany and other countries. One will carry on the business on a purely commercial basis including the sale of various side lines; the other will devote himself to professional ethical pharmacy, drugs, chemicals, galenicals, prescription work, chemical and microscopical analysis, etc.

To bring about such a rather ideal condition of which I am dreaming, it will be absolutely necessary that the education of this ethical and professional pharmacist must be equal to that of the physician. The pre-requisite clause of one year high school education or fifteen Regents counts necessary for the admission to the pharmaceutical schools has greatly benefited and elevated pharmacy. We must however not stop here and should in due time, the sooner the better, require sixty Regents counts for admission to the colleges.

During the year I have been strongly impressed with the following condition in pharmacy which most certainly should be remedied:

1. **Duplicate Specialties.**—The shelves in our pharmacies are continually being loaded with duplicate specialties. No sooner one manufacturer exploits a specialty, than dozens of other manufacturers prepare and market practically the same articles—and the pharmacist, to his sorrow, has to stock them all.

2. **New Chemical Products.**—Although the market is not flooded as much as in former years, although the fake chemicals have disappeared, new chemicals are still being marketed. In my opinion the label should, besides the trade-mark name, contain the chemical name and perhaps the formula and also the dose as a safeguard for physician, pharmacist and patient. The habit of some manufacturers of marketing their preparations in tablet form stamped with initials or in colored capsules most certainly is to be condemned.

3. **Similarity of Names.**—The coined trade-mark names in a great many instances are too nearly alike and might even cause dangerous errors, as for instance, in Lythol, Lysol and Laxol. Similarity in chemical names should also be avoided. Only lately a case came to my notice where a physician prescribed Acid. Thymic, and the pharmacist dispensed Acid. Thymic (thymol).
4. Extemporaneous Galenical Preparations from Fluidextracts.—I most emphatically censure the manufacturing houses for printing on the labels of their fluidextracts not only formulas for the extemporaneous preparation of syrups, tinctures and wines, but even infusions. Imagine an infusion of digitalis prepared from the fluidextract. Such a procedure, in my opinion, ought to be considered a criminal offense. May the originator of this ingenious idea "Rest in Peace." He certainly started the lowering and the downfall of pharmaceutical practice and technique.

Recommendations to the individual practical and dispensing pharmacist.

1. The study of synonyms, pharmaceutical, chemical and botanical.
2. The study of incompatibility, which is very useful behind the prescription counter.
3. The study of pharmaceutical history, especially etymology, origin and history of drugs. It is surprising to learn how few pharmacists know, for instance, the history and origin of such an every-day article as Rochelle salt.
4. Do not advertise and push patent medicines. If you have to sell them, keep them out of sight.
5. Specialize in drugs and prescriptions. "Don't be a jack of all trades, but try to be a master of one!"
6. Strict adherence to the U. S. P. and N. F.
Since these two books have become legal standards, we must strictly adhere to them and suggest improvements if possible. It is also our duty to instil into the physician respect and confidence for these official preparations so that he will prescribe them.
7. More attention should be paid to the storage of drugs, galenicals and chemicals. Even the U. S. P. might pay more attention to this. The average druggist continues to keep his essential oils in stock bottles on the top shelf exposed to the light, and he continues to keep his ammonium carbonate in a drawer and his syrups near the radiator.
8. Preparation of Galenicals.—Above all, the pharmacist, in order to deserve the name of pharmacist, should prepare his own galenicals. From reliable sources I am informed, sorry to say, that 75 per cent. of the druggists in the United States buy all their galenical preparations, including such simples as paregoric, spirit of peppermint and tincture of ginger. It is furthemore absolutely necessary that the pharmacist keep up his stock of U. S. P. and N. F. preparations so as not to disappoint the physician and patient.
9. Pharmaceutical Library.—I shall earnestly recommend to the pharmacist the acquisition of a pharmaceutical library of books and journals. It is surprising to note how little attention is paid to this. How a pharmacist can get along with merely a copy of the U. S. P. and N. F., the latest editions of which he is compelled to possess according to most state laws, I am at a loss to understand.
10. Last, but not least, the retail pharmacist should bring out his individuality. Prove to and impress upon the physician and the public that you fully possess the necessary pharmaceutical knowledge, that you are worthy of their confidence, in fact, that you are a better pharmacist than your competitor. Such is especially true if the latter keeps a cut-rate store, or happens to be a corporation store. This individuality, in my opinion, is the salvation of the small retail pharmacist, especially the one who has a family-trade and who comes in personal contact with his customers. They might patronize the chain or department stores if in need of a cut-rate article, but they will patronize the pharmacist who has gained their respect and confidence, who has established his individuality and who has proven that he pays special attention to drugs, chemicals, galenicals and prescriptions.

This will be a struggle of knowledge against capital.

Let us hope that knowledge will be the victor, at least the saviour of practical pharmacy and dispensing!

Recommendations to the Association.—There are several matters which I have given a good deal of thought during my rather short term of office and which I herewith beg to present for the consideration of the Association.
1. Roll of Honor of Contributors.—As far as I can learn every chairman of this Section has had a great deal of trouble to obtain papers. It is true that through the establishment of the branches and of the Bulletin a great many members can now be reached. My experience, however, has been that, in order to receive an answer, it is necessary to personally address them. A list of those members who have contributed papers or have taken part in the discussions in the Section of Practical Pharmacy and Dispensing, a so-called “roll of honor” would certainly be very helpful to the officers of this Section, and can be transmitted to the following chairman and kept corrected.

2. Distribution of Officers.—If it could possibly be arranged that the three officers of the Section (the Chairman, the Associate and the Secretary), could be selected from different parts of the U. S., this would, in my opinion, be an advantage, as each one could take care of a certain territory. Such was our “modus operandi” this year.

3. Papers to be Refered to the Scientific Section.—As has already been suggested by Dunning at a N. Y. meeting in 1907, I again beg to recommend to refer papers and problems to the Scientific Section, if deemed necessary.

4. Publication of a Recipe Book.—I would earnestly recommend that the Association would publish a “recipe book” as originally proposed (Bulletin, Aug., 1909, p. 248), by Prof. Hynson, the father of the Section of Practical Pharmacy and Dispensing. Much has been said pro and con in our Committee on Unofficial Standards, to whom this matter was referred, but you will find that the practical pharmacists on this committee are in favor of such a book. A “recipe book” of reliable formulas of unofficial preparations is badly needed in the U. S., and it is the duty of the A. Ph. A. to go on record and publish such a book, which incidentally might be a source of additional revenue.

In conclusion let me hope that I have not tired you with my somewhat lengthy address, and also let me hope that the program which I have presented with the aid of my associates, with the co-operation of the contributors will help to make the Richmond meeting the most enthusiastic, the most interesting and the most instructive in the history of the A. Ph. A.: Let it be another verification of the motto of our Association “To improve and advance improvements for the benefit of all.”

The Chair called for action on the address as read.

Mr. Hynson said he hoped no one would object to the “father” of the Section saying a few words in regard to this able address of the Chairman. He simply wanted to call attention to the fact that it was gratifying to see a man of Mr. Raubenheimer’s ability and experience taking so much interest in the Association and its work. He moved that the address be referred to a special committee of three, to be appointed by the Chair, and that this committee’s report be made a special order in preference to the regular program at to-morrow morning’s session, and to be considered at the beginning of the session.

This motion was seconded by Mr. Apple and carried, and the Chair said he would appoint on this committee Messrs. Henry P. Hynson, George M. Beringer and J. P. Remington.

Mr. Raubenheimer resumed the Chair and called on Mr. Sayre to present a paper upon the question of regard for official standards.

Mr. Sayre presented his subject as follows:
"DO PHARMACISTS PROPERLY REGARD THE OFFICIAL STANDARDS?"

BY L. E. SAYRE.

In a communication from an official connected with the administration of the Food and Drugs Law, an opinion was given which shows the attitude of some who may be considered as somewhat disinterested parties, concerning the question of the improvement of the status of pharmacy through the enforcement of the Food and Drugs Law. He said that in order to improve Pharmacy, it would be necessary "to reform the druggist himself." Whether this is a just criticism or not, we need not stop to consider. We are inclined to the opinion, however, that such a view is characteristic of those who are inclined to be pessimistic and may not be an authority on the present or future status of pharmacy. While we are willing to accept the honest criticism of disinterested parties, we must recognize that some disinterested parties have an antagonistic spirit, and their opinion is probably not based upon facts unmingled with prejudice. Our own opinion is that we have in the profession of pharmacy a very large majority who are aiming to observe the standards of the Pharmacopeia, and who are doing all in their power to resist the temptation, to meet fierce competition on the part of the unscrupulous dealer, who adopts disingenuous methods by injecting into the market substandard and illegal materials. This element of competition in the business of pharmacy, the Food and Drugs Law is honestly trying to combat. It is a competition which is one of the greatest hindrances to the profession and a direct detriment to public welfare.

In order to show how far pharmacists properly regard standards, it is evident that one would be obliged to report on all the preparations dispensed by all of the druggists of the United States. This is of course impossible. It is even impossible to accomplish such a task in an individual state. It is, however, possible to make a partial or sectional investigation which may be of some value. As we are, in a measure, familiar with Pharmacy in Kansas, we can show perhaps how far this particular section contributes to an answer to the question. During the past year ending April 5, 1910, over 2100 samples of drugs have been examined in the Kansas Drug Laboratory and in accordance with the requirements of the Kansas Food and Drugs Law, these examinations have been reported. A condensed and partial report of these has been incorporated in another paper before this Association, but for the present paper, we have compiled more definite statistics from the files of the Board of Health, Capitol Building, Topeka, and present these statistics for what they are worth. It should be noted in this connection that inspectors are instructed to collect only suspicious samples, and therefore the percentage of adulterations in the subjoined table indicate only the percentage of sub-standard materials in suspicious drug products collected by the inspector and sent
into the laboratory for examination. I desire to state that since the class known as the saloon druggists has disappeared from the state, the percentage of standard drugs has increased in proportion.

Added to this table, we give a list of samples of Compound Tincture of Gentian, collected in New York, Baltimore, and Philadelphia, sent us by the courtesy of the United States Inspectors at our request. These were collected in order to form some idea as to how uniformly such a common preparation as this official one was made and dispensed in certain sections in the east. We shall tabulate these results as follows, and present them merely for what they are worth:

**Compound Tincture of Gentian.**

It should be noted that inspectors in Kansas are finding that certain disingenuous methods are being used to accommodate a certain portion of the public which creates a demand for cheap goods and which refuses to pay the price for the pure article. It is deplorable to relate, that sooner or later, the dealer surrenders to a temptation to supply this demand. As soon as one yields to it, it opens the door for others, and thus they multiply. Recently we have met sub-standard preparations belonging to this class, preparations such as are used commonly by farmers and those ordinarily kept in the family stores. Singling out only one of these, we would give as an example Spirit of Camphor. The inspectors report that they are finding numerous cases in the State of Kansas where a cheap Spirit of Camphor is dispensed under the following labels:

1. "A mixture—Camphor, Alcohol and Water."

* Made in Kansas University Laboratory from official material and by official formula.
It is needless to say that the administrators of the Food and Drugs Law should do everything in their power to put a stop to such unscrupulous dealings with the public. If we admit of such disingenuous methods of competition, we are introducing an element in pharmacy which is a direct menace to public health.

Report of Drugs and Medicines Analyzed by the Drug Laboratories.

Kansas State Board of Health. Kansas University.

Under the Food and Drugs Law, February 14, 1907, Examination of Suspicious Samples.

</tbody>
</table>

It will be seen from the above that 57.79 per cent. of the drug materials examined were illegal, and but 42.21 per cent. passed the requirements.

In addition to the above there have been examined 458 samples of patent proprietaries, liquors and spices, many of which were misbranded, adulterated or deteriorated. This makes a total of 2,640 analyses reported to this office.

The Chair called for action upon this very interesting paper.

Mr. Cliffe said he did not understand from Mr. Sayre the time covered by the collection of samples; Mr. Sayre responded that it was one year in April last.
Mr. Apple wanted to know if the articles sold to the retailers were to
be dispensed in packages as received from the manufacturer, or sold by
the pharmacists in smaller packages; and if so, how they were to be
labeled. Mr. Sayre responded that they were put out in the case and
labeled, and sold in the original package to the consumer.

The Chair stated that, without objection, the paper would be received
and referred to the Publication Committee, and it was so ordered.

The next item on the program, "The Necessity of a Thorough Under-
standing of the Pharmacopoeia to the Successful Practice of Pharmacy,"
was a paper which the Chair said had been put in print by the author, Mr.
Whorton, of Alabama. That gentleman presented his subject as follows:

THE NECESSITY OF A THOROUGH PHARMACOPŒIAL UNDERSTAND-
ING TO THE SUCCESSFUL PRACTICE OF PHARMACY.

BY C. WHORTON, GADSDEN, ALA.

To some of those who have been blessed with a location near the cen-
ter of pharmaceutical activities and having all around you the most thor-
ough advantages in the great schools of Pharmacy, which have for years
and years sent out, in all directions, men equipped to do this work, my
subject may seem derelict and it might be right that I here offer you an
apology for my selection of such a subject. My experience in Pharmacy
covers only six years of practice and eighteen months in the Alabama
Polytechnic Institute Department of Pharmacy, and I have never had the
time and opportunity to study the needs of our profession outside of my
native state and that loved Southland; but, gentlemen, I am quite sure
this subject applies to us and, if I can offer something that will lead us to
better things within Dixie's borders, I will feel a thousand times repaid
for this effort.

Two years ago I read an editorial from the pen of Dr. Hallberg, in the
official organ of this Association, which was very pessimistic in regard to
the future outlook of the A. Ph. A. in the South, and at that time, I felt it
my duty to take issue with him regarding Pharmacy within my native
boarders. He made the assertion that all efforts to enlist the South in the
work of the A. Ph. A. had proven futile, and that it was merely a waste
of time and effort to fool with us down there.

We are all natural lovers of our own section, where it has been our
fortune to be placed, and there are none of us, gentlemen, who could
hold altogether impartial views; but I can assert most truthfully here
that the A. Ph. A. never made the slightest effort to get me within its
ranks and has never put forth any real telling one to enlist other druggists
of my state and I have had to write to the General Secretary to get in-
formation to furnish other men who were groping in the darkness and who
were seeking their way into this, the great "Source of all good things
Pharmaceutic."
My people are interested in this work and are becoming more and more so each day. They are seeking a way to correct these errors. All that is necessary is a little work of education on the part of this Association, and this missionary work means much to practical pharmacy in the South and a richer field for a great harvest is not open to-day to the A. Ph. A. This Association is the original source of education, and the member who attends from year to year, recognizes after going through each convention that he has learned still more of the greatness of the Pharmacopoeia, the child of this Association. So we find the source of this knowledge, and know that to receive its benefits we must go to the source.

Pharmacy is often given the wrong definition, not only by the laity, but by the members of our profession, and of the medical profession. We so often think of the pharmacist in the light of a mere machine, wound up each morning early, pouring ready-made dopes and nostrums from one bottle to another and counting pills and tablets, that are usually insoluble—thus running automatically until the late hours of night, when the spring completely runs down and he locks up his shop of accommodation until he can pull a few short hours from the land of slumber, which serves only to wind him up for another day of unprofitable toil. This seems to be the conception of some as to the pharmacist, and it seems sometimes to be the pharmacist's own conception of himself.

Let us see how near this comes to filling the place of a real practical pharmacist.

A practical pharmacist is the man who really practices the art of pharmacy. The art of pharmacy is the art of separating from nature's crude store medicines for treatment of diseases, of combining these into suitable preparations for application, of testing and assaying them so as to guarantee their potency and standardize them, and lastly to dispense them as they are prescribed by the physician, who is the expert that diagnoses and applies the remedies.

When we look at existing conditions we see that this lack of pharmaceutical knowledge has taken from pharmacy all that is practical and has left only a part of one division of the art, and that is dispensing; even then he is dispensing some other man's secret combination that is based only upon deception and superstition and not at all upon education and progress.

I can direct you to schools of pharmacy in the South to-day which use a very small compiled book of a few of the U. S. P.'s formulae for their course of education upon the Pharmacopoeia. They are not even required to buy a Pharmacopoeia; and can we wonder that scores of these graduates go out into practice and sometimes continue their career without a copy of this official guide for pharmacists? There he gets about forty easy formulæ to work out in his whole course upon the Pharmacopoeia and
then goes out thoroughly versed upon all things pertaining to this book. He can't even tell when a preparation is official and therefore drifts into the easy-going tide of dispensing anybody's cure-alls.

We have schools advertising to give you all the knowledge that has ever been ferreted out, in pharmacy and chemistry, in four or six months, and and then can we wonder at our professional position?

There are many other gloomy aspects to this situation. A leading druggist in my city has a prescription for infusion of digitalis. He hunted all over hisFldext.bottle for a formula to prepare his infusion. After failing in his search he stepped out of his back door and asked to see my Fldext. Digitalis. I told him I didn't have any of the fluidextract, that my doctors all prescribed the infusion. He informed me that that was what he was hunting and that he knew of no other way of making it. "Where is your Pharmacopoeia?" I asked. His answer came in these astounding words, "I have none, I don't need any, I make all my syrups, tinctures, infusions, etc., from the formulæ on the Fldext. bottle." I found out that he had an old dispensatory of some kind dating back thirty years, but that it had been misplaced and he couldn't find it. Again, a druggist friend of mine had a partner who left him and carried with him some formulæ of the U. S. P. which he has changed from the metric to its equivalent in the apothecary system. So this druggist came around and asked me for this formula already "figured out," as his partner had carried his off and he didn't want to take the time and trouble of "figuring it out" again. The truth is, he didn't know anything about the metric system, the U. S. P.'s adopted system of weights and measures. He couldn't do the simple computing necessary to change the metric into the old system of weights and measures.

Ninety per cent. of the pharmacists of my state can't tell you what aromatic principle it is that gives the characteristic odor to Fowler's Solution, and they will pay usually from fifty to one hundred per cent. more for the product of some pharmaceutical house than they could make it for, when it is a very simple process.

Again, they will run out of the simplest elixir and wait from two to three weeks until they can order and "get in" from some manufacturing house, when they could turn over a few pages in their Pharmacopoeia and make the product in thirty minutes.

I merely refer to these known instances to show you the real conditions as they exist. Their appalling ignorance of the Pharmacopoeia and also the great loss and hardship their ignorance imposes upon the retail druggists and upon themselves.

It is the source of all the greatest obstacles that to-day confront us and relieves our calling of its brightest aspect. It is the grim monster that hovers over our entire business career ready always to grab from our cash register the profits that should go to the substantial support and educa-
tion of our own families, and it is the chief cause of the great nostrum evil that has, at almost too late a date, awakened us to realization of our position in the world of medicine. It has lost for us so much of the confidence once given us by the physician and rightly too has it lost for us this confidence because ignorance should and always will go down before the rigid judgment of education and scientific progress.

After realizing these things we catch ourselves wondering why such conditions exist. Is it the fault of the retail druggist? Who to-day is responsible for the lack of pharmacopœial knowledge? Isn't this a moral issue that involves more than an individual responsibility? The old adage, "What is everybody's business is nobody's business," is so true in this case and we can't wait and expect each individual to clear himself of this indictment of ignorance. We must, as an Association, realize that this great responsibility is upon our shoulders and that we are held for the condition of pharmacy as it exists to-day. That we have been negligent in this work is very evident by these conditions, and it should be almost criminal to find a pharmacy and a pharmacist without the protection, both professional and financial of the Pharmacopœia.

This Association, and this section of it more than any other, should take the initiative in this work and educate American Pharmacy in the real art of this profession and no longer allow men to shield their ignorance with the helmet "A Pharmacist" when a more false position never existed and when he is no more accomplished than a grocery clerk.

Then let the American Pharmaceutical Association take up the work as if it meant to accomplish something, first, by going out after American Pharmacists, bringing them under the educating influence of this great body of scientific men, teach them that the word Pharmacopœia is not a myth and that the art of pharmacy with all its branches belongs exclusively to the pharmacists.

I again say, gentlemen, that to this section, more than any other does this great propaganda work belong, because we discuss and are supposed to promote "Practical Pharmacy" and Practical Pharmacy requires a thorough knowledge and use of the U. S. P.

We here have many discussions of practical work, new and improved methods. Almost all changes in "Modus Operandi," of the most successful pharmacists of this great country are brought before this section. Many suggestions and points of education that we can learn only from the brightest men of our calling are brought to us here and nowhere else. We here, and here only, get the benefit of the successful men of pharmacy, and why couldn't the man who has allowed himself to fall into the pharmaceutical lethargy get the advantage of all this learning and take on new life, become enthused with this work and learn to love the duties of his chosen calling? This is made possible only by his knowing pharmacy and really practicing it.
We enjoy the methods used in preparing medicine, for it is interesting to any investigative mind. It is a source of pleasure to study and work out the different methods of separation. To be original and try to improve on the old ones, at the same time being as perfect in the work. It makes us realize the fact that the Great Creator endowed us all with a supreme power and gives us that great desire down deep in our hearts to excel.

There are many men today within the realm of pharmacy who, if they realized what advantages lay between the bindings of the U. S. P. and knew how soon they could acquaint themselves with at least some of its work and who could realize how interesting the work was after once getting into it, that would eagerly grasp the opportunity. They seem to think that it requires some great divine power to accomplish these things and as in the case of ignorance, all down the ages there is an unseen power that instills doubt and superstition into their very beings. Something wonderful, something magical attached to this great work of combining and preparing medicines. These people that have been singularly blessed with this divine power to do these things are looked upon with awe by the ignorant man of pharmacy and they wonder how they accomplish such great feats as making a fluidextract or even a very simple elixir. That they wield a magic wand over the botanical kingdom and make it yield its healing properties is quite evident; and that they have the aid of the Spirit land in their wonderful accomplishments in chemistry is also evident.

I say to you to day, gentlemen, that there are men in our ranks who are as ignorant as the common man of the laity.

The President of the Alabama Medical Association criticized a speech which one of our pharmacists made before the society in Mobile this year, because the substance of his address was confined to the relative position the doctor and the druggists should assume, when this doctor thought the whole burden of Alabama pharmacists to-day should be to throw off this yoke of ignorance, become free from this bondage of the eastern manufacturers of nostrums, strive to a higher plane of education, arise to the needs of the hour, and become men of pharmaceutical knowledge and therefore men of pharmaceutical power. Then these small grievances of the doctor and the druggist will vanish as the darkness of the night vanishes before the light of the morning sun.

Then we will need no controversy between these professions because the light of education shows both of us clearly our way and then our own profession will accomplish great things and the fetters which to-day bind it will forever be cast from it.

Let us take up the work of helping our brother and when the new U. S. P. comes out in all its completeness, let us each take it upon ourselves to put it into the hands of every pharmacist in the United States, tell him
it is his Bible, it is his guide, it is his stay. Take it, study it and learn to
love it. Apply it to his every want. Then we have really accomplished
something great for "Practical Pharmacy," in this country of ours.

The Chair called for action upon this interesting paper on conditions in
Alabama, and invited discussion upon same, but none was offered.

The paper was ordered to take the usual course.

A paper by R. H. Needham, of Fort Worth, Texas, on the subject of
"Drugs and Preparations Which Go to Make Up Prescriptions," was read
by title, in the absence of the writer, and referred to the Publication
Committee. The same course was pursued in regard to two other papers,
the authors of which were not present, namely, "Quality of Some Crude
Drugs Examined During 1909" by H. Engelhardt and "Quality Versus

"Fluidextracts and Repercolation" was the title of the next paper on
the program, and Mr. Arny, the senior author, presented the subject as
follows:

**FLUIDEXTRACTS AND REPERCOLATION.**

*By H. V. Arny and F. H. Oxley.*

**Introduction.** To discuss the topic already the subject of much study
by some of the master minds of American pharmacy and the cause of
valuable discussions at previous sessions of this Association, seems like
treading upon the holy ground of pharmacy and suggests the adage end-
ing: "where angels fear to tread."

During the past four years, however, one of us had some experiences
with the subject which he offers more by way of suggestion than as a criti-
cal analysis of this most important branch of pharmaceutical manipulation.

With all due respect for the past Committees on Revision and with full
appreciation of their devoted services in the cause of pharmaceutical
progress, study of the processes of preparing fluidextracts given in the
Pharmacopœias (both the eighth edition and that of 1890) we are con-
strained to ask;—are most of these receipts practical?

Those of us who as retailers have made a pint, quart or half gallon of an
official fluidextract and have spent a day in the back room stirring the resi-
dual weak percolate, after distillation of the alcohol—stirring this weak
percolate as it slowly evaporates by water-bath heat—appreciate that the
game is scarcely worth the candle, and this, difficult as it is, when com-
pared with the pharmacopœial directions given for 28 fluidextracts,
" evaporate the residue at a temperature not exceeding 50° C." is merely
a pastime.

As stated by one of us elsewhere:

"As to the 28 fluidextracts, the weak percolates of which are to be
evaporated at a temperature of 50° C., it must be said that this process is
impossible for the retailer. Assuming the intention is to recover the
alcohol by distillation, that operation can take place at 50° C. only when carried on in a vacuum pan, a piece of apparatus the cost of which precludes its use anywhere save in large factories. If the alcohol is to be evaporated and not distilled, the same question as to waste applies here; while the simple act of evaporation of the weak percolate in open air at 50° C. is a task so tedious as to be almost impossible.

In short, this direction "evaporate at 50° C." limits the process to those having vacuum pans, and if rumor be true, our friends the manufacturers, practically the only pharmaceutical possessors of this expensive form of apparatus, do not use the official process any way.

Early in the retail career, one of us appreciated that the process of "percolation with partial evaporation" was not for the retailer, and he turned with gladness to the seemingly complex but in truth exceedingly simple process of repercolation, and in school and out he has been preaching the gospel of repercolation.

But during the past few years he has conducted the experiments reported below and now has to reluctantly admit that unless his data are faulty, his former ideas regarding the efficiency of repercolation must be radically changed.

In short, while the practicability and simplicity of the process makes it still the ideal way of making fluidextracts, the question now before us is, Does the volume of 100 Cc. of the repercolated fluidextract represent the activity of 100 Gm. of the drug?

REPERCOLATION.

In view of the fact that practically every paper on repercolation was read before this Association, a recital of the magnificent work already done on the subject is scarcely necessary. And yet we cannot proceed further without mention of classic papers on it or allied subjects by Squibb (Proceedings, A. Ph. A., 13, 201; 14, 81; 15, 391; 18, 181; 26, 708), by Diehl (Proceedings, A. Ph. A., 20, 681; 27, 727; 28, 424) by Lloyd (Proceedings, A. Ph. A., 27, 682) and by Oldberg (Proceedings A. Ph. A., 32, 388) and the work done by Sayre and associates (Druggists Circular 41, pp. 119, 147 and 212) in connection with the problem of admitting 50 per cent. tinctures into the Pharmacopoeia of 1890.

In discussing these several pieces of research, we will quote only those experiments having particular bearing on the subject of this paper, which, as suggested above, can be summed up in the query: Do 100 Cc. of the repercolated fluidextract represent the activity of 100 Gm. of the drug?

The phrase "total activity" is intentionally omitted for it is not the purpose of the paper to discuss the best means of extracting the full activity of a given drug. That is largely a matter of choice of the appropriate menstruum and knowing full well the amount of patient work done by the members of the past Committees on Revision in this direction, we
are all ready to concede that the official menstrua are usually the best for the particular drug.

Our query can therefore be altered to read:

1. Do 100 Cc. of the repercolated fluidextract contain all the extractive that can be removed from 100 Gm. of the drug by the official menstruum?

2. Does it (the repercolated fluidextract) contain as much extractive as does a fluidextract (from same batch of drug) made by the official (percolation with partial evaporation) process?

Before proceeding to answer these questions from data collected by the writers, a résumé of methods employed by us and of data reported by previous investigators might be in order.

As to methods employed, the most feasible scheme (and that followed with slight differences by all investigators on the subject) was the exhaustion of a certain batch of drug with the official menstruum and estimation of the extractive thus removed from the drug, by evaporation of an aliquot part of the percolate. Having thus established the quantity of extractive in the drug, subsequent batches of the drug were made into fluidextract by repercolation and the amount of extractive in such fluidextract compared with the above mentioned amount of extractive, that was possible to extract from the drug with the official menstruum.

None of us, as yet (save Farr and Wright), have tried what, under our present system of alkaloidal standardization, would be the most scientific method of comparison; assay of the particular drug and assay of the finished product made by processes of the Pharmacopœia. As far as the present writers are concerned, the work of assay of about fifty samples of drug or fluidextract was beyond the limited time at their disposal. But one of the main objects of this paper is to suggest to the next Revision Committee an attempt to collect data on this very important method of comparison by systematic co-operation.

It seems to us that our friends, the manufacturers, could throw most important light on this topic without prejudice to their own interests or publicity of that part of their special manipulations which have commercial value.

As to the estimation of extractive in the percolates, all the investigators adopted the obvious plan of evaporating an aliquot part of the liquid at a temperature low enough to prevent possibility of decomposition. Not to burden this paper with details, the most carefully thought plan was that suggested in the paper by Professor Sayre (D. C. 41, 147), to which those interested are referred. Since the only drug used by the writers was the comparatively stable gentian, their method was evaporation of 10 Cc. of the liquid in tared beaker glasses in a drying oven, kept steadily at temperature between 100° and 110° C., and of course each estimation was controlled by running a duplicate.
The question of complete exhaustion is possibly worth a paragraph. Squibb (A. Ph. A. 26, 713) says the drug is never completely exhausted; that 5 per cent. to 10 per cent. of the activity always remains in the marc; that hence it would be good to percolate 8000 grains of drug to get one pint of fluidextract. As to the amount of percolate required for exhaustion of drug he reports (A. Ph. A. 18, 164) that 16 troy ounces aconite take at least 13 pints of percolate for complete exhaustion; that 16 troy ounces wild cherry are exhausted when 16 pints of percolate have been obtained; and that 16 ounces of cinchona show bitterness even in the 17th pint of percolate; the figures referring to the menstrua directed by the Pharmacopoeia of 1860.

These figures are evidently his extremes, for later (A. Ph. A. 26, 726) in a general summary of conclusions he states that to exhaust a drug, percolates weighing from 3½ to 7 times the weight of the drug must be obtained. Sayre (D. C. 42, 119) goes deeply into this important subject, citing among others, Campbell's unproven claim that he could exhaust 16 troy ounces drug in 16 fluid ounces percolate; Squibb's figures from 6 drugs each of which took 3 to 4 times as much percolate to exhaust as amount of drug used; Farr and Wright's work showing that in percolating 100 grammes each of twelve different alkaloidal drugs, there was an appreciable amount of alkaloid in each case in the fifth 100 Cc. of percolate.

These varying statements are impressive as showing what great influence the skill and speed of percolation has on amount of percolate necessary to produce exhaustion. Sayre quotes from the testimony of one of us (Proc. A. Ph. A. 40, 169) as follows:

"We note that he found it necessary, in order to extract the drugs used, to obtain as a minimum amount about four times the volume of percolate, that is to say, in extracting buchu, for example, four troy ounces of the drug required 17,625 fluidounces of percolate to exhaust it. In some cases the volume of percolate required, was more than six times the volume represented by the weight of the drug. For these experiments Mr. Arny claims no rigid scientific exactitude—they were confined to practical operations in a retail pharmacy 'with all the care possible under existing disadvantages.'"

To this might be added the statement that in our gentian work reported below, the average drug is exhausted only after percolate amounting (in Cc.) to six times the amount of drug (in grammes) had passed, while in some extreme cases the ratio was one to eleven.

Testimony of previous investigators seems to agree with our conclusions that 100 Cc. of the repercolated fluidextract do not represent the activity of 100 grammes of drug.

Passing over Squibb's figures in Proceedings A. Ph. A. 13, 218, which shows work done before he had devised his process of repercolation; in the Proceedings A. Ph. A. 26, 722, he reports a repercolation of cinchona
in which 32 avoirdupois ounces of the drug containing 358.33 grammes extract yielded 32 avoirdupois ounces of fluid extract, containing 252.44 grammes of extract; only 70.3 per cent. of what its strength should have been.

Again (Proceedings A. Ph. A. 26, 731) he reports a repercolation of four batches of 8 troy ounces of cimicifuga containing 316.95 grammes extract with the result that the combined (four) reserve portions, approximately 30 fluid ounces contained 253.89 grammes extract. Since, from figures just given, 30 troy ounces of the drug should contain 297 grammes extract, the 253.89 grammes extract in the 30 fluid ounces of finished fluid extract, showed a marked deviation from 100 per cent. strength.

Diehl (A. Ph. A. 26, 685) states that the first 12 fluid ounces of percolate from 16 troy ounces of drug in simple percolation, average about 60 per cent. of the extract in that 16 troy ounces of drug.

The repercolation work of Sayre and his associates, since based on 50 per cent. tinctures, does not offer exact comparison with work done by us, but it likewise emphasizes the difficulty of securing a 100 per cent. product on the original lines of repercolation.

**EXPERIMENTAL PART.**

During three winters, selected groups of students were allotted the manufacture of 200 Cc. of fluidextract of gentian by repercolation, all using the same stock of gentian (in 30 powder). At the same time from the same batch of gentian, a fluidextract of gentian was prepared by percolation with partial evaporation, care being taken to secure complete exhaustion of the drug. This "U. S. P. Fluidextract of Gentian" was taken as the norm; the amount of extract obtained by evaporation of 10 Cc. of this being compared with the amount of extract from 10 Cc. of the repercolated samples.

As each year a new batch of drug was employed, the results have to be grouped in three tables.

Do not these figures show that while, as we already know, a 100 per cent. product cannot be obtained by simple percolation of a kilo of drug to a liter of percolate, a product stronger than 100 per cent. can be obtained by collecting the first 500 Cf. percolate from a kilo of drug?

Do they not suggest the advisability of consideration by the next Committee on Revision of a modified variety of "percolation with complete exhaustion" based on obtaining half as much percolate (in Cf.) as the amount of drug used (in grammes); comparison of the weight of extract obtained from 10 Cf. of this percolate with the weight of extract from 10 grammes of drug and final dilution of the (stronger) percolate to same strength as dry?

Such a plan would be much simpler than the present official process and would insure a full strength (100 per cent.) product. Whether it would be cheaper to throw away half the activity of the drug left in the marc than to waste the alcohol necessary to extract it; whether, in short, the plan should include a saving of weak percolate for future use, future experimentation will show.
In conclusion the writers wish to acknowledge the work of Miss Jessie G. Rosen in connection with the experiments of the first year.

Pharmaceutical Laboratory, Cleveland School of Pharmacy.

CONCLUSIONS.

From the above tables it is seen that in only three cases (No. 7 of Table I and Nos. 9 and 10 of Table II) did the repercolated fluidextract approach in strength the fluidextract made by percolation with partial evaporation and whether this was due to some accidental manipulation on the part of the operator, or whether it can be taken as a sign of possibility of securing a genuine 100 per cent. product is an interesting question. The obvious conclusion, however, is that under the care exercised by the average manipulator, a 100 per cent. preparation is not obtained.

It emphasizes the need of some sort of standardization whether the operation is large or small; nor is this necessarily a tedious assay process,—a simple preliminary exhaustion of 10 grammes of the drug with the menstruum, evaporation of the percolate to a dry extract and weighing of same, constituting the needed standard of comparison, the only exception to this plan being with those fluidextracts containing glycerin.

Is it possible to obtain a 100 per cent. preparation from a drug by simple percolation?

Certainly: if one only stops the percolation at the right time.

During the past few weeks, a superficial investigation of the problem was made by entrusting to five specially competent seniors, batches of the same gentian used in Table III. Three of the men extracted batches of 50 grammes to 50 Cc. percolate, while the other two extracted 100 grammes to 50 Cc. percolate. The results are given below as Table IV.

Mr. Sayre said he did not know of any subject more fruitful of an animated and prolonged debate than the one that had just been brought to the attention of the members. He was afraid from the rapidity with which the paper had been read that possibly some of the members did not understand the exact import of it. He supposed the author was aware of the fact that such a process as he suggested was already in vogue, and he thought Campbell was the originator of that process. He thought the Committee of Revision had already gone over this subject, and that
the main object of the Committee had been to produce as far as possible uniform preparations in the hands of the average druggist. Whether the average druggist had arrived at the point that the author assumed he had he did not know; but it was certainly very desirable that the subject should be again submitted to the Committee of Revision, and he was glad, indeed, to have the paper presented.

Mr. Scoville said he had made a little study of repercolation in his day, and he had come to the conclusion that there were three factors involved: First, the drug; second, the menstruum, and third, and most important, the operator. When drugs percolated easily, like capsicum and the resinous drugs in general, repercolation could be used with excellent results. Mr. Arny had selected a drug which represented the average drug, and that was all right; but with some drugs this could not be done. As to the factor of menstruum, when some drugs were moistened with aqueous or weakly alcoholic menstrua they would swell up to twice the bulk they normally occupied; they would absorb their own weight or body; and certain drugs, when packed in a percolator, would absorb the menstruum, pint for pint, and one could not be sure that the percolate represented the drug, because the bulk was too much. On the other hand, if the menstruum was strongly alcoholic, the drug might shrink instead of swell; and yet there would be a better chance to get at a concentrated percolate by a strong than a weak solution of alcohol. The third fact was the operator himself.

Mr. Scoville said he had found that the results were quite in proportion to the relative firmness with which the drug was packed. If it was packed firmly, quite a strong percolate would be the result, but if packed loosely it would give a weak percolate. He thought this was a problem for the Pharmacopceial Committee to deal with. The Pharmacopœia must have a uniform process, and must have a process as little dependent on the operator as possible. Repercolation would give good results with a good operator, and poor results with a bad one.

Mr. Remington said that the subject of percolation to the practical druggist was, at all times, a most interesting one. He had happened to be among Dr. Squibb's assistants when he brought out his process of repercolation. He was perfectly familiar with his experiments, which lasted over a year, and he thought it might be interesting to state a few facts in connection with this process. The process of repercolation was the result of Doctor Squibb's years of experience in developing a process that would save alcohol. That was the first proposition, to save alcohol, and make an economic process. Consequently, he realized the necessity of avoiding the use of heat—a very important consideration—because he realized that heat, as a rule, with most drugs, produced some dissociation of principles, and Mr. Remington said he thought all would admit that heat was undesirable in making fluidextracts. Right after the war, when alcohol was
very expensive—many plans were devised, by manufacturers particularly, for making fluidextracts that would save alcohol. Repercolation was picked up rapidly by the manufacturers. After Dr. Squibb published his process, Mr. Remington said he thought nearly every manufacturer in the country used repercolation in some form or other—and it was used to a large extent to-day. When it came to the study of drugs, and especially official drugs, this subject had to be viewed from a pharmaceutical standpoint, and a process had to be given which would be generally applicable to nearly every drug. He thought experimentation would show that 75 to 80 per cent. of the valuable constituents of a drug would be found in what was called the "reserve percolate," and many manufacturers during the war considered it sufficient, and some do to-day, to take 1000 Gm. of drug and slowly percolate with the proper menstruum, and get 750 cubic centimeters of fluidextract and throw the exhausted drug away—because they believe that that would make a fluidextract.

Mr. Remington went on to say that the reason the pharmacopoeial formula was constructed as it was was because it was intended to be used by retail pharmacists all over the United States—not manufacturers; and that Mr. Scoville and Mr. Army had struck a key-note when they stated that the process depended upon the skill and care of the operator. The character of the menstruum and the slowness of the percolation had a great deal to do with the complete exhaustion of the drug. If the drug was packed loosely in the percolator and the menstruum allowed to go through rapidly, instead of getting 75 per cent., a 40 per-cent. extractive only might be obtained. On the other hand, if it was percolated very slowly, very much better results would be had. Therefore, it would depend very largely on the personal equation of the operator.

Mr. Remington said that he wanted to say, in closing, that where it was realized that these formulas for fluidextracts were to be sent throughout the whole country, to be used by men of little or no experience in percolation—men who were ignorant—the Pharmacopoeia had nothing else to do but, in base-ball vernacular, to "play safe"; that was, the setting apart of a reserve percolate representing 75 to 80 per cent. of the value of the drug without the use of heat. Then the operator should go on with the percolation and evaporate the least valuable portion of the percolate to a soft extract. Some drugs were not injured by a higher temperature, but with drugs which contained volatile or easily dissociated principles the heat would be objectionable.

And so they had to introduce a safe process, taking into consideration all these facts. Mr. Remington went on to say that he thought it would be a very dangerous thing to put in the Pharmacopoeia directions to start with 1000 Gm. of a drug and percolate slowly, and get 750 cubic centimeters of reserve and throw the residue away. In the hands of the manufacturer, he would say that it might be all right, for they use many checks. The oper-
ator on a large scale must have had a great deal of experience, and he could be safely trusted: but for the retail druggist it would hardly be safe to put such a process before him.

Mr. Apple said he wanted to call attention to a fact about repercolation he had not heard mentioned here, and that was, that one must take into consideration in the process of repercolation the length of time elapsing since the last lot was made and the next lot repercolated. In discussing with physiological chemists the question of determination of standards, they admitted that these products would deteriorate almost as soon as manufactured, the rapidity of such deterioration depending upon the conditions under which the finished products were stored.

Mr. Hallberg said that the manufacturer on a large scale who reserved 75 per cent. of the volume of the percolate, of course, did not throw the remainder of weak percolate away. He preserved that and used it to moisten his drug. But the retail druggist could not do that. The objection to the process, the way the weak percolate had been concentrated by evaporation, was, that the evaporation caused a change in the alcoholic strength, and to that extent induced precipitation. This would be largely avoided by the modification of the process of the National Formulary. There was quite a difference in the processes of the N. F. and the U. S. P. When the weak percolate was concentrated to a solid extract and that was added to the reserve, which was already a saturated solution, at once a precipitation was induced, which could be prevented by addition of sufficient original menstruum to make it up to the required volume. After having once started precipitation, it could not be retarded. By the N. F. process there was no precipitation. Therefore, he advised that the process of the National Formulary should be the process of the Pharmacopœia for fluidextracts.

Mr. Hynson said he wanted to ask Mr. Amy what steps were taken to standardize these extracts, and said he would like to know if time was not a factor. He asked if a good deal of the varying effect of repercolation was due, not to menstruum, but to time.

Mr. Amy said that his idea in presenting this paper was the hope that just this sort of discussion would come out. He had recited his own personal experiences, and he wanted to get these of others. But if it was considered by the members that this criticism of the pharmacopœial process was an unwise one he would unhesitatingly say that his paper should not be published. The point was this, that the U. S. P. process, according to his notion, was impracticable. He agreed that repercolation was an ideal process, but the question was, would it give 100 per cent. fluidextract. The manufacturer could obtain it, but he was talking about the retail pharmacist operating on a small scale. He said the third point he wanted to bring out was one which was not clearly understood. He wanted to make it clear that in the process of repercolation, working with small
batches of drug, say 100 grammes, instead of getting the activity of 100 grammes of drug in 100 cubic centimeters of the percolate, one operator might get the activity of 75 grammes and another of 50 grammes of the drug in 100 Cc. percolate. Mr. Arny said that in none of the literature that he had seen on repercolation was any scheme suggested for standardization. His scheme was, in brief, to first take 10 grammes of the drug, percolate it to exhaustion with the official menstruum and learn amount of drug extract by evaporation of the percolate. This learned, the proper amount of the drug (say 1000 grammes) was to be percolated with the official menstruum until the percolate measured half as many cubic centimeters (in above proportion 500 Cc.), as grammes of drug used. 10 Cc. of this percolate was to be evaporated and comparing yield with extract with that from 10 grammes of drug the percolate could then be diluted to conform to drug strength. He said, of course there were drawbacks in the plan. If the percolate contained glycerin, then of course, standardization by evaporation would not be feasible.

As far as speed was concerned, he said he carefully regulated the percolate to drop from three to five drops a minute. As to Mr. Scoville's proposition as to the individuality of the operator, Mr. Arny asked the question whether the average operator could really make a 100 per cent. fluidextract by repercolation.

Mr. Hallberg suggested as an answer to this question, that drugs which could not be assayed chemically should be tested physiologically.

Mr. Arny said that the gentleman misunderstood his point. His question was, could a fluidextract (by repercolation) be made by the retailer, operating in a small way, and was there any simple way for estimating the strength of the finished product?

The Chair stated that the next paper on the program was by Hiland Flowers, on Experimental Percolation, but the author was not present. He had sent, however, some samples for the inspection of the members, such as strophanthus, nux vomica, etc., and especially called attention to a sample of opium, made in a very few minutes by the process described. The Chair said he thought it would be wise to refer to the Scientific Section to find out whether there was anything in pressure percolation, as he understood in Germany it had been turned down. He said he would entertain a motion to refer these samples to the Scientific Section.

Mr. Hallberg said he thought all the papers on percolation had been read, and that the discussion was to be concentrated on all of them at once, and he would be sorry to see the time taken now to discuss this paper separately. He moved that it be received and read by title, and referred to the Publication Committee.

It was so ordered.

A paper by Paul J. Waldner, on "Criticisms of the U. S. P. Tinctures," was read by title and referred, in the absence of the author.
"Tincture of Cantharides" was the title of a paper next presented by the writer, Wilbur L. Scoville:

TINCTURE OF CANTHARIDES.

BY WILBUR L. SCOVILLE.

The U. S. Pharmacopoeias of 1870, 1880 and 1890 directed tincture of cantharides to represent 5 Gm. of drug in 100 Cc. of tincture. In the Eighth Revision this strength was doubled to accord with the international standards for potent drug tinctures, viz., that such tinctures should represent 10 Gm. of drug in each 100 Cc.

Since several foreign pharmacopoeias (French, German, Japanese, etc.) recognize a 10 per cent. tincture of cantharides, it was not thought necessary to prove the practicability of this change, and it was adopted without special investigation.

The assay of cantharides has never reached the stage of simplicity and accuracy that applies to alkaloidal assays. The processes for cantharides assay are mostly long and tedious, and the results are not thoroughly satisfactory. In 1907 Greenish and Self published in the Pharmaceutical Journal (Vol. 24, p. 324) a new process, which is a decided improvement on the older ones, but which requires considerable care and practice to yield reasonably concordant results. In describing their process they give considerable attention to the solubility of cantharidin in different solvents. In alcohol the solubility is variously reported as "very insoluble," "slightly soluble," "1 in 952," "1 in 3300," and "1 in 1330," by various observers.

Since the alcohol solubility of cantharidin is a vital point in tincture of cantharides, I first tested this in the following way: 0.2 Gm. of cantharidin, in fine crystals, were shaken during several days, in a mechanical shaker, with 100 Cc. of alcohol. The undissolved crystals were then collected, dried and found to weigh 0.125 Gm., leaving 0.075 Gm. dissolved by 100 Cc. of U. S. P. alcohol. This corresponds to a solubility of 1 in 1333 (w. v.) at a temperature of 23° to 25° C. and agrees closely with the reported solubility of "1 in 1330" (w. v.).

Cantharides is reported to contain from 0.5 per cent. to 1.0 per cent. of cantharidin, when of good quality, and 100 Gm. of such cantharides will contain 0.5 to 1.0 Gm. of cantharidin, requiring 660 to 1330 Cc. of U. S. P. alcohol for dissolving it. The question of what influence the other constituents of cantharides may have upon the solubility of cantharidin in an alcoholic solution then remains.

To determine this four samples of Russian cantharides were obtained, assayed by the process of Greenish and Self and tinctures prepared from them. Cantharidin is slowly soluble in most solvents and special care was exercised in making the tinctures. Percolation was conducted very slowly, the collecting of a liter of tincture, including the preliminary maceration, occupying from 8 to 17 days. The percolates were shaken each day, to
keep them well mixed and prevent supersaturation. When finished, each tincture was nearly clear, but on standing (1 to 5 months) each had deposited a small amount of whitish sediment of a granular character. After standing a few days, to permit any insoluble matter which might be present to settle, each was assayed. Following are the results:

**C. S. P. Tinctures.**

In each instance the tincture represents two-thirds to one-half, or less, of the total cantharidin in the drug used. The tincture from Drug No. 4 was made by more rapid percolation (8 days in process) than the others, and evidently is not a fair representative. But if this be eliminated, the results for the other tinctures are very disappointing.

Cantharidin is found in cantharides both free and combined, and in most assay processes a mineral acid is used to liberate the combined cantharidin.

Since the above tinctures do not in any case represent a saturated alcoholic solution of cantharidin, the question remains whether the unextracted cantharidin may be combined in the drug, or simply insoluble in the tincture.

Cantharidin was found to be soluble in 125 parts (w. v.) of glacial acetic acid, and a second series of tinctures was made, with an acidulated menstruum.

A tincture of No. 2 drug made with a mixture of 1 volume of glacial acetic acid and 15 volumes of alcohol showed 0.051 per cent. of cantharidin by assay. Three tinctures were then made of the three drugs, using a mixture of 10 volumes of glacial acetic acid and 90 volumes of alcohol as a menstruum. Following are the results:

**Acidulated Tinctures.**

</tbody>
</table>

These results are much more satisfactory than than the U. S. P. tinctures, but are still a little below the expected strength. These tinctures have all remained bright, showing no trace of sediment.
Greenish and Self showed that cantharidin volatilizes with steam, and it is possible that a material loss occurs in the preliminary evaporation of the tinctures, though the temperature was not allowed to exceed 50° C. at any time. They also showed that there is some loss when solutions of cantharidin in benzene or in chloroform are evaporated, the amount of loss depending upon the rate of evaporation of the solvent, and the amount of heating. 200 mls. of tincture were evaporated to dryness for each assay, and it is reasonable to conclude that some loss may occur at this stage. Time does not permit of testing this point before this paper is due.

The results, however, warrant two conclusions: First, that the U. S. P. tincture does not represent 10 per cent. of a good drug, even when prepared with exceptional care. Second, that an acid menstruum is much better than a neutral one for the extraction of cantharides. Glacial acetic acid has the double advantage of being a good solvent for cantharidin, as well as freeing the combined cantharidin, but there is reason for thinking that the best effect of the acid is its liberation of the combined cantharidin. Furthermore, since combined cantharidin is inactive as an irritant, the acid menstruum may be expected to yield a more active as well as a stronger tincture.

Mr. Remington said that he thought tincture of cantharides was used by pharmacists chiefly in making hair preparations, as it has been known for many years that acetic acid was an excellent solvent for cantharidin. He thought in some pharmacopoeias vinegar was designated for that purpose. He expressed the opinion that Mr. Scoville’s paper would be received by the Committee and studied; but, after all, he did not think it would be satisfactory to introduce the acetic menstruum.

Mr. Seltzer, referring to Mr. Remington's suggestion that tincture of cantharides was used mainly for hair preparations, said he was surprised to see how often it had been dispensed in the last four or five years, that it was quite frequently used in prescriptions in his locality.

Mr. Hallberg expressed surprise that Mr. Scoville had experimented with an acid; he thought he should have used an alkali. He should have used caustic potash. Cantharidin was an acid, and formed a soluble salt with alkali. There would be no difficulty in complete exhaustion by the use of an alkaline menstruum.

Mr. Scoville replied that acetic acid was one of the best solvents for cantharidin—better than chloroform; yet he could not get an extract of cantharides with acetic acid that represented the drug, and the only way he could account for that was, that the extractive had an influence on the solubility.

He said he would like to ask Mr. Hallberg if he thought an alkaline tincture of cantharides would be an active preparation—a proper preparation of cantharides, to use as it was used. He himself did not think so, as he did not believe it would be active enough.
Mr. LaWall said that a great deal of work had been done by Mr. Beringer on this subject, as set out in a paper presented before the New Jersey Pharmaceutical Association some years ago, and that he had arrived at the same conclusion Mr. Scoville had. He said this paper of Mr. Beringer's had never been very widely copied, although it was published in the proceedings of the New Jersey Association.

A paper on "Abstracts from the Squibb Laboratory Note Books," was next presented by the author, Mr. Dunn:

**ABSTRACTS FROM THE SQUIBB LABORATORY NOTE BOOKS.**

**JOHN A. DUNN.**

These few notes are given as an addition to those read before the Section on Practical Pharmacy and Dispensing at the fifty-seventh annual meeting of the American Pharmaceutical Association held in Los Angeles, Cal., May 16-21, 1909.

**DILUTED HYDROCYANIC ACID, ASSAY.**

The weighing out of exactly 5 Gm. entails a certain loss of hydrocyanic acid. It is also desirable to avoid diluting to a given measure and taking a part of this diluted solution as required by the U. S. P., VIII. To prevent loss of hydrocyanic acid during weighing put 25 Cc. distilled water in an 8-oz. Erlenmeyer flask and add 5 Cc. $\frac{N}{10}$ KOH, V. S. Stopper the flask and weigh. Now add quickly from a pipette about 3 Cc. of the acid, stopper and weigh again, to get weight of sample. Add a little sodium chloride and then run in from a burette $\frac{N}{10}$ silver nitrate V. S. with frequent agitation until a permanent turbidity appears. This is best seen by titrating with the flask on some dark surface.

The number of Cc. of $\frac{N}{10}$ silver nitrate V. S. multiplied by 0.005368 and then by 100, and this figure divided by the weight of the sample, gives the per cent. of absolute hydrocyanic acid in the sample.

**RESIN OF SCAMMONY.**

For the past few years we have been quite unable to obtain in the home market or abroad any of the old-fashioned Virgin Scammony, and the question now arises, What are we going to do about it? Will the pharmacopœial authorities permit us to resort to the extraction of the root as the British Pharmacopœia directs or will we have to seek for it in other directions?

In connection with this matter we are told that the root of *Jalapa fustiformis* (*Ipomoea orizabensis*) and the so-called Tampico jalap (*Ipomoea simulans*) yield to alcohol a resin chemically identical with that obtained from the scammony root, and that much if not most of the "scammony" resin found in the market to-day is probably obtained from these sources. Following up this suggestion, we determined to make some experiments
ABSTRACTS FROM THE SQUIBB LABORATORY NOTE BOOKS.

along these lines, and as the result of our investigations we find the yield of resin from the various sources to be about as follows, using official alcohol as a menstruum for extraction:

From the so-called Mexican scammony (Ipomoea orizabensis)—

Dark root, about .................................. 13 per cent.

Light root, about .................................. 12 per cent.

From scammony root, about .......................... 8.4 per cent.

One and one-half times its weight of alcohol completely exhausted the true scammony root, while three times its weight was required for the Mexican roots.

The two resins differ greatly, not only in physical properties, but also in appearance and odor, as well as in their behavior toward the various solvents. The resin from the Mexican roots is lighter in color, and the odor is that of resin of jalap. The resin from the scammony root has the “scammony” odor and color.

FERRIC HYPOPHOSPHITE.

Test for Foreign Heavy Metals.

The U. S. P. test reads as follows: “If 1 Gm. of the salt be dissolved in about 25 Cc. of boiling water, by the aid of sufficient hydrochloric acid, added drop by drop, etc.” We suggest that nitric acid be used at this point instead of hydrochloric acid for the following reason: When hydrochloric acid is used and the iron is later precipitated with a slight excess of ammonia water, the precipitate is greenish in color and it is difficult to filter from it a clear solution. When nitric acid is used the precipitate obtained is red-brown, the filtration is rapid and the filtrate clear and colorless.

DETANNATED TINCTURE OF CINCHONA.

Take

Ground cinchona No. 60 ................................ 200 Gm.
Magnesia, calcined, light ................................ 34 Gm.
Ammonia water ........................................ 300 Gm.
Diluted alcohol, q. s.

Directions.—Mix the ground cinchona with the calcined magnesia, then moisten with all of the ammonia water and allow the mixture to stand 24 hours, then remove to trays and dry thoroughly in a hot room and again reduce to about a 60 powder. Now macerate with sufficient diluted alcohol for six hours, then pack it firmly in a percolator and proceed as with the regular tincture cinchona U. S. P., using diluted alcohol throughout and adjusting to U. S. P. alkaloidal strength and making the final product just acid to litmus paper. This formula is offered for the reason that the formula of the National Formulary, III, will not work out a pro-
duct of full alkaloidal strength. In our experience, covering four trials, only one-quarter to one-third strength was obtained.

**SOLUTION OF IRON OXYCHLORIDE.**

Experience with this solution since our report to you at the last meeting suggests that solution of iron chloride be used instead of solution of iron tersulphate which we suggested at that time. The precipitated iron hydroxide from solution of iron chloride seems to be more readily soluble in the small quantity of hydrochloric acid than the one obtained from iron tersulphate solution.

**ELIXIR OF IRON, QUININE AND STRYCHNINE PHOSPHATES.**

This preparation when made by following the U. S. P. exactly gives a product which is brownish-green in color and soon becomes quite dark. We have found that this is due to the ammonium acetate and the exacting directions of the U. S. P. to have the finished preparation exactly neutral. When the ammonium acetate is reduced in quantity, leaving sufficient only to insure a permanent solution of the alkaloids, and the final directions to neutralize are omitted, a preparation is obtained which has a nice green color when finished and keeps a good color for a sufficiently long time, so that a pharmacist making a portion, say once a month, would not experience any trouble. The Pharmacopoeia should state that this preparation darkens with age, and that its efficiency is not affected thereby. We suggest the following figures:

<table>
<thead>
<tr>
<th>Use of ammonium carbonate</th>
<th>5.1 Gm. instead of 9 Gm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use of acetic acid</td>
<td>16 Gm. instead of 28.65 Gm.</td>
</tr>
</tbody>
</table>

Do not follow the U. S. P. directions, "and if the solution be acid to litmus paper, neutralize exactly with ammonia water."

Mr. Francis said there was an item in this report that attracted his attention, and that was with reference to the resin of scammony. He said there had been for the last year or more a great scarcity in the Oriental scammony root, and as a result the scammony as manufactured in the United States had been manufactured from the Mexican scammony. In fact, he had seen very few samples offered in the last six months that could be identified as coming from the Oriental root. He had seen the scammony offered from the Mexican article, which could be had very much cheaper. He thought there was very little evidence tending to prove that the Oriental scammony was better or worse than the Mexican drug, but he believed that he was correct in the statement that the Pharmacopoeia did not permit the use of Mexican scammony.

Mr. Hallberg thought this question of scammony was an important one, and said that all who had to make compound cathartic pills and compound extract of colocynth knew that the price of scammony had been so high
the last few years as to almost prohibit the use of the drug. He asked if there was not some way to determine whether or not this extract of the drug from the root was equal to the resin from the virgin scammony.

Mr. Dunn said the experiments along this line were interrupted by a fire that had occurred in their establishment, but that the consensus of opinion of those who had joined in the experiments was, that it was an active resin. No accurate conclusions had been arrived at, however.

The Chair stated that the next paper on the program was one on some U. S. P. preparations, by John K. Thum, of Philadelphia. The author was not present, and the paper was simply received and referred for publication:

A paper on "Preservation of Volatile Oils," was presented by the author, Charles H. LaWall.

A NEW METHOD OF PRESERVING VOLATILE OILS.

BY CHARLES H. LAWALL.

In 1904, while the writer was engaged in examining a number of substances purchased from bakers' supply houses with the view of ascertaining whether they complied with the Pennsylvania State Food Law, a bottle marked "Oil of Lemon" was found upon examination to contain a mixture of equal parts of oil of lemon and cottonseed oil. The dealer was proceeded against in the course of time and the case being settled, the incident was temporarily forgotten. During the winter of 1906, when a number of specimens were overhauled with a view to discarding the more ancient of them, this bottle was found and upon observing the odor the writer was surprised to find that it had not become in the least terebinthinate, but had a fresh and agreeable odor, notwithstanding the fact that two years had elapsed and the oil had been kept in a partially-filled bottle in a closet in the warmest part of the laboratory. Mention of the fact was made in a lecture to the junior class in pharmacy in the institution with which the writer is connected, and one of the students, Mr. Cecil Beam, of Moundsville, W. Va., offered to take the subject up for his thesis. He accordingly made a number of experiments upon oil of lemon, using varying quantities of fixed oil and exposing the samples to different conditions of temperature. At the time of Mr. Beam's graduation in 1908, when his thesis was handed in, it was accompanied by his samples which were more than a year old then and which conclusively showed the effectiveness of even so small an amount as 1 per cent. of fixed oil in completely retarding the acquiring of a terebinthinate odor. Mr. Beam's samples have been again examined recently (1910) and they are still in a perfectly fresh condition as regards odor, while his unpreserved samples submitted at the same time are in a badly decomposed state.

In the spring of 1909 the writer made some additional experiments upon several other oils in order to try out the method still further. Speci-
mens of the oil of orange, lavender flowers and peppermint were selected as being especially prone to deteriorate. They were mixed with varying proportions of fixed oil, using olive oil instead of cottonseed oil, as being of a more bland and permanent character (olive oil had also been used by Mr. Beam in his experiments), and while the samples of the pure oils have undergone marked changes for the worse, the samples containing the fixed oil are all in an excellent state of preservation.

I would therefore conclude that the addition of a small proportion of fixed oil (5 or 10 per cent.) to an easily decomposable volatile oil would be a satisfactory method of retarding deterioration. It must be remembered that an oil thus preserved could not be sold as a pure oil and that when used in manufacturing due allowance must be made for the diluting material, which, being insoluble in alcohol, readily separates and can be filtered out of a preparation.

Mr. Eliel said that, in his experience, he had found that when fresh packages of oils, like oil of orange and other oils belonging to the citrus family, were opened and only part of same used, if diluted with an equal amount of alcohol, there was no difficulty in keeping the residue—the alcohol being taken out, of course, when the oil came to be used. So far as oil of peppermint was concerned, if the oil was U. S. P. to start with, he did not believe it would be necessary to add anything to preserve it, except to take proper care of it and store it in a cool, dark place, with a fairly even temperature. The U. S. P. directed that the oil be a redistilled oil, and as all the resins were removed in the process of redistillation, he thought possibly there would be no change if the oil was right at the start. He said he had been told by distillers of oil that a good quality of oil improved by age. He did not know how true this was, never having tried it out, but so far as the citrus oils were concerned, he thought the alcohol method was by far the preferable method for preservation.

Mr. Eberhart asked Mr. LaWall whether the addition of any fixed oil had this effect, as well as olive oil. Mr. LaWall replied that he was unable to answer, because he did not make any experiments, except those mentioned.

Mr. Wharton, of Alabama, said he had put the oil in small ounce containers and sealed it up, and put it in a cool, dark place, and he had been very successful with it.

The Chair stated that he had had the same experience as Mr. Eliel, only he had found the alcohol used must be absolute alcohol. He had made an experiment with oil of sweet orange, and had opened a bottle very recently, a bottle three years old, after receiving Mr. LaWall’s paper.

Mr. Eliel said that, in his reference to alcohol, he took it for granted that it would be understood he referred to absolute alcohol; that he did not use a hydro-alcohol as a diluent.
The Chair next called for a paper on "Solution of Mercury Biniodide," by H. A. B. Dunning, of Baltimore. The writer presented his subject as follows:

**SOLUTION OF MERCURY BINIODIDE IN OIL.**

BY H. A. B. DUNNING.

Some years ago when the hypodermic injection of preparations of mercury and mercury compounds came into vogue for the treatment of syphilis and syphilitic disorders, various soluble salts of mercury in aqueous solution, suspensions of metallic mercury, and various insoluble salts of mercury suspended in fluid-oily combination were being used for subcutaneous injection, I conceived the idea that an oily solution of some mercury salt would be the ideal preparation for the purpose.

In my search for an oil-soluble mercury salt, the only satisfactory one which I found is the red mercuric iodide. In the literature consulted, I found a statement that this salt is soluble in fixed oils, which led me to experiment with solutions of the same in the following fixed oils: olive oil, oil of sweet almonds, cotton seed oil, oil of sesamum, castor oil, and also with petroleum oil.

Of the fixed oils mentioned, excepting castor oil, oil of sesame retained the larger percentage, 0.4 per cent., of mercuric iodide in solution, and seemed to have the most satisfactory characteristics for the purpose.

Castor oil, which will take up and retain more than 1 per cent. of mercuric iodide, is regarded as having too great viscosity to be satisfactory. While petroleum oils will take up the salt by heat, but little is retained in solution on cooling.

Some physicians in Baltimore have used a 0.4 per cent. filtered and sterilized solution of mercuric iodide in sesame oil over a period of four or five years, and are doing the same at the present time. Anaesthesine in small quantities (by some physicians) was deemed desirable to combat the pain of treatment.

Recently, at the instigation of a physician desiring a preparation of greater strength, I have prepared a solution containing 1 per cent. of the mercury salt in a mixture of olive oil two-thirds and castor oil one-third. According to the reports, this preparation has proven quite satisfactory, with the exception of the pain accompanying the injection, no worse, however, than is observed when injecting any of the preparations of like character. The addition of any local anaesthetic is perhaps advisable, because of the prolonged use and danger of habit-forming.

The following formulas are those to which I have referred in this paper:

<table>
<thead>
<tr>
<th>R Mercury biniodide</th>
<th>0.2 Gm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anaesthesine</td>
<td>0.1 Gm.</td>
</tr>
<tr>
<td>Oil of sesame</td>
<td>50.0 Gm.</td>
</tr>
</tbody>
</table>
Triturate the finely-powdered solids with a small portion of oil of sesame to a smooth paste, then add the remainder of oil and mix thoroughly; introduce into suitable container, and heat in water, shaking frequently until solution has been effected, filter while hot, pour into a glass-stoppered bottle, then sterilize by immersing in water and heating to boiling for one hour.

\[
\begin{align*}
R & \quad \text{Mercury biniodide} & c.50 \text{ Gm.} \\
& \quad \text{Castor oil} & 18. \text{ Cc.} \\
& \quad \text{Olive oil} & 32. \text{ Cc.}
\end{align*}
\]

Triturate mercury biniodide to fine powder, and rub to smooth paste with a portion of mixed oils, and then add remainder of oils, introduce into a suitable container, and heat in hot water with frequent agitation until solution has been effected, filter while hot, and pour into glass-stoppered bottle, which is now sterilized by immersing into water and heating to boiling for one hour.

After several weeks' standing the product of this latter formula shows, sometimes, deterioration, to the extent that some of the mercuric iodide crystallizes out. I have recently prepared a sample of same strength in equal parts of castor oil and olive oil for observation, which will in all probability remain permanently a solution.

Mr. Asher said he was somewhat interested in this paper; that he had heard olive oil was used, and upon analysis they had failed to find mercury, and the conclusion reached was, that, in the process of making, the mercury had decomposed in some manner. He asked Mr. Dunning whether the solution contained mercury iodide as represented in the original formula. He said that in the journal of the American Medical Association he had seen where samples of this preparation had been analyzed in their laboratory, and they had failed to find anything but a trace of mercury. He wanted to know whether any further work had been done in this connection, other than as stated in the paper.

Mr. Dunning said that he was in a position to say that it had been tested out physiologically, as Mr. Hallberg suggested for testing these things. He thought he could say, without exaggeration, that his firm had made for the physicians in Baltimore a hundred pints of this solution, without any complaint as regarded the expected mercuric reaction or otherwise. He had not taken the trouble to test it chemically, since he had really felt that there was no occasion for such estimation.

Mr. Asher said the reason he had asked the question was, that in one of the chemical laboratories of his city they had this preparation to pass on by analysis, and the chemist, a personal friend of his, said he was unable to find mercury in a preparation on the market claimed to contain one per cent. of mercury.

Mr. Hallberg suggested that this formula be referred to the Committee
on National Formulary, as he thought this preparation was one that ought to be in that work. This motion was seconded by Mr. Arny.

The Chair suggested that this formula had originated in France, and that the work Mr. Dunning had done upon it was to be commended.

Mr. Dunning was inclined to take issue with the Chairman upon this proposition, and said he was at work on this preparation about the same time that the French preparation was put forth.

Mr. Alpers asked if any of the members had any experience with solution of mercury salicylate—whether anyone had attempted this solution in oil. Physicians in New York City wanted to use it in hypodermic work.

Mr. Dunning said before the solution in oil was in use, they had put up large quantities of mercury salicylate in petroleum oil, in sterilized mixture, and it was frequently ordered as solution of mercuric salicylate and oil. This was carelessness on the physician’s part, of course.

Mr. Seltzer said that mercuric salicylate in oil is not quite clear. They had used a water bath, and did not have much trouble, and although not a clear solution, they had dispensed it in that way.

The Chair suggested that this might be called an emulsion. Regarding the aqueous solution, he said he had used that occasionally, but it could only be made of a certain percentage.

Thereupon, the motion to receive Mr. Dunning’s paper and refer to the Committee on National Formulary was put and carried.

Mr. Apple read the following paper:

**IS THE U. S. P. STANDARD FOR PEPSIN SATISFACTORY TO THE PRACTICAL PHARMACIST?**

*BY FRANKLIN M. APPLE.*

This query undoubtedly will appear to be uncalled for by a number of those of our calling—due to their acceptance of the present standard as the highest one possible, or owing to their absolute indifference to the subject.

The standard of this animal product is presumed to represent the results of careful investigations along the line of proteolytic ferment, and when the purity rubric of the Pharmacopoeia demands, generally, that chemicals shall be 97 to 99 per cent. pure (for 99 per cent. standards are very frequently noticed in the U. S. P. requirement), the operators in pharmaceutical processes, in the retail pharmacies, accept without a murmur and most complacently the difficulties encountered as unavoidable ones, when working with U. S. P. pepsin.

To my mind the standard for any chemical or product recognized by the U. S. P. should be such as to meet the most exacting requirements of the manipulators in pharmaceutical laboratories, and be as free from undesirable adherent or adulterating matter as possible, and this is especially desirable when the foreign matter is of animal origin.
When employing pepsin in the laboratory to prepare such preparations as solution of iron peptonate and manganese, or glycerite of pepsin, should we not have at our command the very best and purest pepsin that science can produce?

Almost everyone is familiar with the very harsh criticisms hurled at the liq. ferri. peptonati cum mangano, N. F., owing to the undesirable odor of the same, which has rendered it absolutely worthless as a remedial agent, although the proprietary preparations of the medicinal agent are largely prescribed by the medical men. In the revised formula for this preparation recommended by Mrs. Harrison, fresh albumen is utilized as the source of the peptone, being acted upon by pepsin, hence the purity of the latter should be as high as it is possible to make it.

In experiments covering a number of years, I have invariably found that a 1:6000 pepsin (practically a double strength one) has simplified very materially operations in which pepsin was employed, and we never use the official strength pepsin, except upon prescriptions for powders, when the bulk must be given in order to avoid suspicion and controversy.

In the U. S. P. (eighth revision) will be found the following statement: "If it is desired to use a diluent for reducing pepsin of a higher digestive power to that required by the Pharmacopoeia, sugar of milk should be employed for this purpose." This appears to me in the light of a joker, when the high standard required for the zinc salts, for example, are considered in comparison, and when the literature of pharmaceutical houses that prepare pepsin and its preparations is carefully searched, for, at as remote a date as 1900, it is acknowledged by one manufacturing house that it was then "offering pepsin of any desired strength from 1:1000 to 1:15000 at a relatively uniform cost (so much per thousand) of digestive power."

If a 1:15000 pepsin cost just as much per thousand digestive power as a 1:1000 one, why should the pharmaceutical manipulator be led to use a 1:3000 product when the purer products are available at no additional costs, relatively?

It is acknowledged that, usually, it is the impurities in chemicals that cause the majority of the obscure pharmaceutical problems, hence why should the pharmaceutical manufacturers be content with a product with a low purity rubric when far better ones can be procured at no relatively greater cost?

With such high-test products available it is possible to meet the standard of the U. S. P. (VIII), to reinforce a very low-grade, undesirable product with a high-test one, so as to pass the requirements. This should not be tolerated in the next revision of the Pharmacopoeia, as it should stand for the best obtainable only, thus giving laboratory workers better crude materials with which to manufacture superior products.

It may not be generally known that the standard for crude pepsin when it was first prepared was 1:10 to 1:12, which would not permit of very
elegant pharmaceutical products being made from them, and the standard was gradually improved until it reached 1 : 3000, where it has been anchored for some time; but the time has come to abandon this obsolete standard for a much higher one.

If in preparing glycerite of pepsin, N. F., which is recognized as one of the best (if not the best) liquid form of pepsin, a high standard pepsin be employed, the process will be greatly simplified, and the product will be freer from undesirable foreign matter, making it a preparation that will appeal to the most exacting practitioners.

I will digress just a trifle and call your attention to the following statement appearing in the U. S. Disp. (19th edition) relative to the dosage and therapeutic value of pepsin, U. S. P. (VIII): “The usual dose of pepsin is from ten to fifteen grains, and it is plain that the solvent power of less than such an amount is too trifling to be of any value in sustaining the digestion of an adult . . . that it has been given to adults in ridiculously small doses, and that a drachm (3.9 Gm.) of the ordinary commercial article is a moderate dose.”

To administer 60 grain doses of a powder, when it is possible to get the same therapeutic effect from a small bulk of a higher quality medicament is to step backwards from the day of alkaloids and concentrated galenicals to the days of crude drugs and impure chemicals, and no progressive pharmacist or therapeutist will endorse such an act.

In order to make it possible for the practical pharmacist to prepare concentrated pharmaceutical products, the standard for the crude materials must be raised to the highest practical basis, and I feel positive that it is not making an unreasonable demand when I suggest that the standard for pepsin in the next issue of the U. S. P. shall not be less than 1 : 6000.

Give to the practical pharmacists of our country such crude materials that they can prepare creditable products such as will compare most favorably in every respect with the preparations sent out by large manufacturing establishments, in which they realize the importance of using only the purest and most concentrated crude materials.

The accusation has been repeatedly made that the U. S. P. (VIII) is a manufacturer’s handbook and does not meet the needs of the rank and file of retail pharmacists and therapeutists: hence every effort should be put forth in the forthcoming revision to prevent a recurrence of the accusations, and one way to do so is to make the standard for crude drugs of vegetable, mineral or animal origin as high as moderate cost will permit.

To my mind the present low standard for pepsin is due more to oversight or lack of interest in this product than to any other cause; but I sincerely hope that the next standard of purity will be such that practical retail pharmacists will have at their command, as the official product, a far more satisfactory one for manufacturing purposes, with which they can prepare more elegant preparations, with less trouble and annoyance. Give
the great army of practical pharmacists a better opportunity to manufac-
ture a greater percentage of their galenicals than at any time heretofore—
thereby benefiting the greatest number of interested parties.

The Chair invited discussion upon this paper, but none was offered.

The next paper called for was one on "Syrup on Wild Cherry," which
was presented as follows by the writer, Mr. Dunning:

SYRUP OF WILD CHERRY.

BY H. A. B. DUNNING.

Syrup of wild cherry prepared in accordance with the formula appear-
ing in the Pharmacopoeia, 1890 revision, produces a preparation essentially
superior to the product obtained if 1900 revision formula be used.

I make use of the term essentially in this connection because I believe
syrup of wild cherry should be regarded as a very desirable vehicle or
solvent for certain drugs and chemicals to allay coughing and that therapeu-
tically the syrup is of little value.

As a vehicle the 1890 preparation is superior because, due to the differ-
ent mode of preparation, it is a beautiful wine-red solution, while in strong
contrast the 1900 preparation is a sickly reddish-brown tinged with yel-
low. Furthermore, the 1890 preparation is more highly flavored, both as
to odor and taste. It keeps quite as well as the 1900 preparation, and
may be criticised only as regards the greater percentage of extractive
matter, particularly of tannin character held in solution. It seems to me
that there can be no great objection to the presence of tannin in the syrup
because it is rarely used in combination with anything which is incompat-
ible with it.

I therefore most earnestly suggest to the Pharmacopoeia committee that
they consider the advisability in the next revision of substituting the 1890
formula for the 1900 without change, except perhaps that the moistened
wild cherry be macerated the required time loosely packed in a suitable
percolator in which it is subsequently packed without removal.

Mr. Hallberg moved to accept the paper, and stated that the formula
that the author referred to as being in the Pharmacopoeia of 1890, he had
put there.

The Chair stated that it was a good formula.

Continuing, Mr. Hallberg said he did not originate it, but he had pre-
pared it from a formula of John W. Reeder, a graduate at the Philadelphia
College of Pharmacy in 1876, this being his thesis, the extraction of wild
cherry bark with water and glycerin. This would give a better extraction.
It made a nicer preparation, and a better therapeutic preparation, and he
considered that it was a "piece of vandalism" to take it out in the last
revision. So far as he knew, no pharmacist would use the present process
a second time. He proposed that there be added to the suggestion in
the last paragraph of the paper as to macerating the required time, the
clause—"and protect it from all contact with metals."
The following papers on the program were, in the absence of the writers, read by title and referred for publication:

The Chair stated that the next item was a paper on the subject of "Kerosene in Pharmacy," by W. R. White, Associate on the Committee.

Mr. White presented his paper as follows:

KEROSENE IN PHARMACY.

BY WILLIAM R. WHITE, NASHVILLE, TENN.

Kerosene, aside from its use as a heating and illuminating agent, has so far as I know never received any recognition as a therapeutic agent, although it has been employed as a domestic or household remedy for various ailments for some time.

In the last few years however, it seems to have been gaining a place in pharmacy and may in the future become a valuable and popular remedial agent.

Kerosene was formerly obtained by the dry distillation of coal and other bituminous substances and for this reason was called coal oil, but since the discovery of petroleum the name has been applied almost exclusively to the illuminating oils obtained from this source, which have been refined by distillation between 150° C. and 220° C. By consulting numerous authorities I find that the following names are often used as synonyms for kerosene: coal oil, rock oil, solar oil, paraffin oil, mineral oil, carbon oil, oil petre, earth oil, photogene, eupione and refined petroleum. Chemically, kerosene is a mixture of hydrocarbons belonging chiefly to the paraffin series.

It has a specific gravity ranging from .744 to .829, boils above 77° C. and has a flashing point from 62° C. to 68° C.

Kerosene mixes well with chloroform, ether, turpentine, the volatile oils and most of the fixed oils, but will not mix well with castor oil, glycerin or alcohol. It will dissolve 4 or 5 per cent. iodine if warmed and agitated, the solution resembling very much a commercial preparation and will take up a much larger per cent. if mixed with chloroform.

The disagreeable taste and odor of kerosene has always been a drawback to its use in pharmacy. The bad taste can be greatly modified by sweetening it with a small percentage of saccharin. To deodorize it however is a more difficult task.
I have experimented considerably with this object in view and find that most any volatile oil such as cassia, cajuput, cloves, peppermint, winter-green, camphor, bitter almond, or mirbane, will disguise its odor. I also tried to deodorize it by shaking it with acid solutions of such oxidizing agents as potassium permanganate, potassium dichromate and potassium chlorate, and then decanting and filtering it through freshly slacked lime; but none of these entirely deodorized it, although they improved it a great deal. Potassium chlorate gave the best results of the three. Kerosene with an alcoholic solution of potassium hydrate turns the alcoholic solution red and almost completely deodorizes the kerosene.

By the liberation of nascent hydrogen in kerosene I got an odor resembling that of onions. On investigating the effects of kerosene when taken internally I learned that if free from sulphur and the lighter hydrocarbons that it produces no bad effect. Blyth on Poisons reports a case where a woman drank a pint of it with suicidal intent and recovered; a slight pain in the stomach and a little febrile disturbance being the only bad effects.

I have known it to be taken internally in numerous cases of croup in children in from one-half to teaspoonful doses with good results. It is also taken frequently for coughs and colds, usually mixed with sugar. One man in my State has ascribed to it laxative properties. Dr. Granville S. Hanes, Professor of Rectal and Intestinal Surgery in the University of Louisville, Ky., has experimented with kerosene extensively as a rectal injection for amebic dysentery with excellent results. He uses a half-gallon or more at a time.

He says, "I have employed the ordinary coal oil for more than two years in the treatment of amebic dysentery; I have used it in more than 200 cases—not more than 50 however, affected with amebic dysentery—and in no case have there been any injurious effects from its use. It is decidedly the best agent I have ever used for the local treatment of amebic dysentery. Patients will receive much larger quantities of coal oil than they will of any aqueous solution, and will retain it a greater length of time."

The most important use of kerosene as a therapeutic agent has been in its application externally as a liniment, both alone and in combination with other agents, for rheumatism, lumbago, neuralgia, etc. I herewith submit a formula of a liniment containing 72 per cent. kerosene which may also be used internally for cramp, colic, etc.

Camphora ................................................................. 1. Gm.
Ol. Menthei Piperite .............................................. 0.5 Cc.
Ol. Gaultheriae ................................................... 5 "
Ol. Caryophylli .................................................... 2. "

Ol. Terebinthinae .................................................. 4. "
Kerosene ............................................................... 72. "
Mix and filter.
Oil of cloves, oil of cassia, and carbolic oil dissolved in kerosene makes a splendid toothache remedy. Kerosene has already gained a rank as one of the best insecticides. Its use for this purpose has been tested in connection with the war on the mosquito during the last yellow-fever outbreak. Evelyn Groesbeeck Mitchell in "Mosquito Life" says an ounce of it sprayed over 15 square feet, kills not only larvae and pupae but catches the adults and is therefore by virtue of its simplicity, cheapness and efficiency the best larvacide for many purposes where its odor is not offensive. Kerosene does not harm fish or aquatic insects that do not breathe at the surface, and acts well in salt water. An emulsion of kerosene can be cheaply made by the following formula:

\[
\text{Soft Soap} \quad \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cd
Cuban pharmacists liked it and prescribed it—in fact, specialized that particular preparation. It was simply put in to combat a certain proprietary preparation on the market at the time. He said he certainly would like to have this matter referred by this Association to the Committee on Revision of the U. S. P. He thought it would be a good subject to take up, the question of substituting phosphoric acid for citric acid, and the leaving out of sodium nitrate. He made an elegant preparation in this way.

The Chair stated that the next paper on the list was one by Mr. Berger, of Florida, on "Cuban Practical Pharmacy and Dispensing."

Mr. Berger presented his subject as follows:

**CUBAN PRACTICAL PHARMACY AND DISPENSING.**

BY E. BERGER, TAMPA, FLA.

The recent translation of the U. S. Pharmacopoeia by Dr. Guillermo Diaz, professor of pharmacy in the University of Havana, and its adoption by the Cuban government, has met with a very favorable reception, which the sales of the book indicate.

Pharmaceutical progress on the island has been slow, due to Spanish colonial misrule and oppression, and the U. S. Pharmacopoeia is the first bright light on their horizon for the progress of pharmacy. Although the Cuban has not made much progress, he nevertheless is a thorough pharmacist and learned in his profession. His business is conducted on ethical lines. Prescriptions are filled, and nothing but drugs, chemicals, pharmaceutical preparations, and but very few patents are found in his store. His professional standing is on a par with that of the physician. On coming to this country he, however, is quick to adapt himself to conditions, and extends his business even into more extensive lines of sundries and notions than we do. However, he has never successfully handled one important branch; this is soda water. To educate the Cuban public to drinking soda has proven a failure. Their soft drinks are very limited and are called "refrescos." They are mixtures of fresh fruit pulp, sugar, cracked ice and plain water, and are sold in their cafés.

The Cuban apprentice starts, as we used to, by washing bottles, scrubbing mortars and sweeping the store, in other words, from the ground up; and my experience with Cuban applicants before the Florida Board of Pharmacy indicates that they are better prepared and have a better fundamental knowledge than our American applicants. Neatness, cleanliness, and a full realization of the importance of their work are cardinal principles with them. The number of successful Cuban applicants before our Board is very much greater than that of Americans. This shows up particularly well when we take into consideration that they have studied the Spanish pharmacopoeia and Spanish text-books only; neither does the physician nor the druggist in Cuba study Latin, and most of our examiners take the position that they can make no allowance for this, and that the Cuban
must answer the same questions which the American applicant does. We attempted to refuse these men (very few speak English) our examination except in the English language. However, we reconsidered our decision, and they can take the examination as heretofore through the aid of an interpreter.

A very small percentage of the Cubans and Spaniards in this country, especially where they live together in separate parts or suburbs of a city, learn English. They have their own commercial establishments of all kinds, and their own physician who seldom speaks English, and of necessity require a druggist who can administer to their wants.

The Cuban druggist manufactures nearly all of his pharmaceuticals, and some chemicals and essential oils, although since American intervention several of our large pharmaceutical houses are doing considerable business on the Island. On moving to our country, they follow suit in this particular, as well as in our business methods, and patronize the pharmaceutical houses liberally.

Prescriptions are written in Spanish with the possible exception of the time honored R, although many Cuban physicians use the letter F, being a contraction for Formula. The following is a characteristic prescription:

```
R Riaz de Ipecacuana contundida
   Agua
   Infundase.
   Ioduro de sodio
   Carbonato de Ammonio
   Jarabe simple
   Dis. y. m.
veinte centigramos
sententa y cinco gramos
Despues de enfriamiento filtrase y anadase:
veinte y cinco centigramos
dos gramos
veinte y cinco gramos
```

```
Cucharaditas
Una cada dos horas

Sept. 6—1909

Dr. ———

Translated.

R Ipecac Root, Bruised
Water
Make an infusion.
Sodium Iodide
Ammonium Carbonate
Simple Syrup
Dissolve and mix
.20
75
After it has cooled, filter and add:
.25
2
25

Teaspoonfuls
One every two hours

Sept. 6th, 1909

Dr. ———
```

Counter prescribing is not an issue in Cuba due to the high professional standing of the pharmacist and his consequent close and friendly relations with the physician. With the translation and adoption of our Pharmacopoeia and the constantly growing trade relations with Cuba it is but natural that our methods of practice will be gradually adopted. Our Association in my opinion
could do a great work of mutual benefit by increasing its membership among Cuban druggists on the island, and if possible, instituting a branch there.

Mr. Hynson moved that the paper take the usual course, but that the Secretary call attention of the Council to the suggestion in the paper in regard to increasing the membership in Cuba. He thought that matter might be taken up with considerable success, and with benefit to this Association and to Cuban pharmacy. He suggested that Mr. Berger be sent over there to form a local branch, as he could talk Spanish.

The Chair so put the motion, that the paper be received to take the usual course, and that the attention of the Council be called to this matter, and the motion prevailed.

The following papers were read by title and referred for publication:

The Chair stated that Mr. Eberle wanted to say a few words about the last paper presented.

Mr. Eberle said that the addition of glycerin was taken into considera-
tion as a preservative. This was made use of in the British Pharmacopoeia, and it had been found that glycerin does preserve the preparation for a longer time than alcohol alone. But the improvement was in the use of two alkalies at one time thereby saving loss of ethyl nitrite. This particular preparation was tested on two occasions, about two months apart, and the last time it was only very slightly deficient. The main point was, however, the use of the two alkalies at one and the same time thus avoiding loss of the ethyl nitrite incident to the usual manipulation.

The Chair stated that this concluded the program of the session, of some thirty-five papers, and it was only a quarter past six. He called for nomination of officers of the Section as the final order of business.

Mr. Hynson said he was interested in the Association, and he feared that nominations made at this time would not be altogether judicious, and he hoped the Section would entertain a motion to name a nominating committee, composed of the Ex-Chairman, Mr. Apple, and Messrs. Dunn-
ing and Seltzer, this committee to make report at the next session.

Mr. Wilbert thought this suggestion was out of order, as in conflict with the By-laws, but the Chair suggested that no harm could be done by it, and if any one desired to bring in other nominations later, it could be done.

Thereupon the Chair put the vote upon Mr. Hynson’s motion, and it prevailed.

Upon motion of Mr. Hynson, the Section then adjourned.
SYMPOSIUM ON THE PHARMACOPOEIAS OF THE WORLD.

SECOND SESSION—FRIDAY EVENING, MAY 7, 1910.

Chairman Raubenheimer called the Section to order at 8.30 p. m., and asked Associate White to preside, while the Chairman read his Introduction to the Symposium of the Pharmacopoeias of the World, arranged for this session.

Mr. Raubenheimer presented his subject as follows;

SYMPOSIUM ON THE PHARMACOPOEIAS OF THE WORLD.

My first thought was that such a symposium should be held in the Scientific Section. But after due consideration and as the result of correspondence with prominent members of the Association I reached the conclusion that it should be held before the Section on Practical Pharmacy and Dispensing. My aim is to make this an international reunion of the various pharmacopoeias, and I consider it unique in this respect that the retail pharmacists, scientific pharmacists, pharmaceutical editors, professors, teachers, literary pharmacists, physicians, government officials and also manufacturing pharmacists have been selected from different parts of the country to take part in this symposium. In fact, I even went beyond the boundaries of the United States, as, upon the advice of Professor Remington, I asked one of our foreign members, Prof. T. Ladakis, of the Syrian Protestant College at Beirut, to review the Pharmacopoeia of Greece. Professor Ladakis was good enough to inform me that no official pharmacopoeia was to be found in Greece, and that the only pharmacopoeia recognized by the Greek government was one published in the year 1837, which was based on the Bavarian Pharmacopoeia at that time.

According to such an authority as Schelenz, Geschichte der Pharmazie, page 680, the Munich pharmacist, Xaver Landerer, who went with King Otto I to Athens, became the reorganizer of Greek pharmacy, and, together with John Bauros and Joseph Sartorius, published the first edition of the Greek Pharmacopoeia, which was followed by a second edition in 1868. Professor Ladakis also wrote me that the Greek Pharmacopoeia was official for some years, but had ceased of late to be an official book, and that the French Codex and the German Pharmacopoeia are used unofficially. The German Pharmacopoeia was even translated into Greek in 1893.

A Greek Pharmacopoeia was to have been published some time ago, but its issuance was deferred for the time being in the belief that an International Pharmacopoeia would be published to take the place of the different National Pharmacopoeias. The pharmacopoeia used at present in Greece is a book edited in 1899 by Prof. A. K. Dambergis, of the University of Athens, and it is recommended to the students of medicine and pharmacy by the National Council of Greece. This Dispensatory does not give any official requirements, but is a compilation of the preparations of the German, French, British and other Pharmacopoeias. I have noticed lately in
foreign pharmaceutical journals that a new edition of this Dispensatory
has been issued. The "American Druggist" of April 25, 1910, contains
an excellent review of Professor Dambergis' manual.

The pharmacopoeias to be reviewed in this symposium are those of
Austria, Belgium, France, Germany, Great Britain, Hungary, Italy, Japan,
Mexico, the Netherlands, Russia, Scandinavia—i. e., Denmark, Norway
and Sweden; Spain, Spanish America—i. e., Chili, Venezuela and Argenti-
tine; Switzerland and the United States, a total of twenty. As may be
seen, the scope of this symposium is a large one, and I am in hopes that
even a little knowledge of these various pharmacopoeias will be helpful to
the members of the A. Ph. A. as well as the U. S. P. Revision Committee.
The Pharmacopoeial Convention of the coming week has certainly stirred
up the medical as well as the pharmaceutical profession, including the
wholesaler, the retailer and the manufacturing pharmacist. It is indeed a
pleasure for me to state that numerous pharmaceutical associations have
elected as their delegates to the convention practical retail pharmacists,
men who know the conditions in retail pharmacy thoroughly, men who
will attend the convention and who will present suggestions and recom-
mandations. I would also remind you at this point that the Congrès
International de Pharmacie is to be held at Brussels, September 1 to 5,
1910. Every pharmacist who loves his profession ought to join this Con-
gress, as the fee for active membership is only twenty francs. The
Congress has issued among the eight propounded questions the following:
"The utility and necessity of a large number of practical pharmacists on
the committees charged with the revision of the pharmacopoeias and the
establishment of an International Pharmacopoeia." Let us hope that in
the next Pharmacopoeial Revision Committee practical pharmacy will be
represented by practical pharmacists and members of the A. Ph. A., espe-
cially on the sub-committees on galenicals. In all civilized countries they
calculate with the same figures, they measure with the same instruments,
they study along the same lines, and they practically employ the same
drugs, chemicals and galenical preparations for the relief and cure of dis-
 ease. But there have existed in the pharmacy of the different nations vast
differences, and the several people have clung tenaciously to their re-
spective standards. You will fully realize the wide range in such a daily-
used preparation as Syrup of Ferrous Iodide when I tell you that in former
years it contained: 0.5 per cent. FeI₂, Belgium and France; 1 per cent.,
Mexico and Switzerland; 10 per cent., United States, Denmark, Sweden; 12.2 per cent., Hungary.

The often-used Dover's Powder, which in most pharmacopoeias contains
10 per cent. of powdered opium, formerly ranged from 8.8 per cent.,
Spain; 14.3 per cent., Austria and Italy; 16 per cent., Belgium.

And how dangerous these various preparations might be can well be
illustrated by the tincture of strophanthus, which although of 10 per cent-
strength in most pharmacopoeias, is 2.5 per cent. in Great Britain, and was 3 per cent. in the United States and 20 per cent. in France and Mexico.

Tincture of aconite is 5 per cent. in Great Britain; 10 per cent. in most pharmacopoeias and was 20 per cent. in France and Hungaria, and was 35 per cent. in United States. Perhaps the best illustration of all showing the variations in the strength of official preparations is diluted hydrocyanic acid which, although of 2 per cent HCN. strength in most pharmacopoeias, did contain 1 per cent. in Japan, Mexico and France; 2.5 per cent. in Belgium, and even 10 per cent. in Spain and Portugal.

It was due to this difference in strength that in 1893 the late Dr. Bruno Hirsch compiled his excellent book, "Die Verschiedenheiten gleichnamiger officineller Arzneimittel," giving the variations in official medicaments with the same name.

At the Paris International Pharmaceutical Congress in 1900, Prof. Alexander Tschirch, of Berne, who, I am very glad to state, has been elected an honorary member of the A. Ph. A. at the Richmond Meeting made the following proposition: "To have a comparative table prepared showing the difference in strength of medicines having the same name in different pharmacopoeias; to have this table distributed to pharmacopoeial commissions, academies of medicine, pharmaceutical colleges, etc., with the request to take the matter into due consideration at their next pharmacopoeial revision and to adopt, as far as possible, a uniform standard of strength, and when differences still remain, to call attention to such in a footnote." This brought about the International Conference for the Unification of Formulas of Potent Medicaments at Brussels, September 15 and 20, 1902, and at which the United States was so ably represented by Dr. Fred B. Power and Dr. Horatio C. Wood. Every pharmacist ought to be acquainted with the resolutions of this International Conference, or, as it is shortly called, Brussels Protocol, as it has been published in the pharmaceutical press, also in Hager's Ergänzungsband, and in Bulletin No. 49 of the Hygienic Laboratory of the Public Health and Marine Hospital Service September 20, 1902, and November 29, 1906, the days on which this agreement was signed will be memorable ones in the annals of pharmacy as they mark the advent of a new era, the fruition of attempts covering nearly fifty years. All the different nations, with the exception of Germany, Great Britain and Russia, which will follow shortly, have since 1904 published new editions of their pharmacopoeias, books which, as Professor Tschirch so well said, are the mirrors of their times.

When I proposed this symposium it was stated that not many retail pharmacists were acquainted with any of the foreign pharmacopoeias. I am glad to state the contrary. For the benefit of those not acquainted with these books, copies are here for inspection and for the benefit of the dispensing pharmacists in general. I beg to remind them that
in a Canadian or British prescription a pint means twenty fluidounces, and that in Continental prescriptions liquids are not measured, but are always weighed. Most Continental prescriptions are written in Latin, with the exception of a few, as f. i., the French, Spanish and Italian, which are written in the language of the respective countries. The strengths of the various galenicals, especially of the potent preparations, have been made uniform, according to the Brussels Protocol, and no further change will be required. It must also be borne in mind that Continental alcohol instead of being 95 per cent. strong is only 90 per cent., and diluted alcohol 68 to 70 per cent. In the foreign pharmacopœias the strengths of the acids also differ considerably. Acidum aceticum means glacial acetic acid. Acidum aceticum dilutum must not be confounded with our 6 per-cent. acid, as it ranges from 20 to 50 per cent. in strength. The U. S. P. acidum aceticum dilutum of 6 per cent. strength corresponds to the acetim of the foreign pharmacopœias. In connection with this, permit me to suggest that the excellent Report on the Progress of Pharmacy in our Proceedings by Professor Diehl could be still further improved if the strength of the articles which differ materially from the U. S. P. standards could be stated, as is done for instance, in Dietrich’s Manual. I do not mean to put any extra work upon our hard-working reporter, but I do know that only a very small minority of our members would take into consideration the strength of the article when following a formula quoted from a foreign pharmaceutical journal. The odor and especially the color of a great many galenicals also differ largely from the U. S. P. preparations. Good examples of this type are Fowler’s Solution, which is colorless in most of the foreign pharmacopœias; tincture of nux vomica, being prepared directly from the seed, has a yellowish color. The foreign pharmacopœial nomenclature also differs widely from our own, and this is well worth remembering in compounding foreign prescriptions. Essence de canelle on a French prescription does not mean essence of canella, but oil of cassia cinnamon. Tinct. strychni or strychnos is not tincture or solution of strychnine, but our tinct. nucis vomicae. Ammoniacum is the official Latin title in the Spanish Pharmacopœia for ammonia water of 10 per cent. strength and must not be confounded with gum ammoniac. Natrium chloratum is not, as ordinarily supposed, sodium chlorate, but sodium chloride, NaCl.

Precipitœ blanc can be taken for our white precipitate (ammoniated mercury), and also for precipitated calomel. I cite these few examples to show that in order to compound foreign prescriptions correctly and to prepare foreign galenicals the pharmacist must be well acquainted with the foreign pharmacopœias.

In summing up I beg to call your attention to the fact that the high position which the pharmacy of the United States occupies at present in International pharmacy can only be kept up if we adopt the progress of the other nations. The United States, England, Germany and Austria
certainly lead in practical pharmacy, France and Switzerland being more productive scientifically, than practically or technically. It is a well known fact that the chemical and, to some extent, also the botanical part of the U. S. P. VIII is far superior to any of the foreign pharmacopoeias. The galenical part, however, decidedly needs improvement. The review of these foreign pharmacopoeias in this symposium will impress us with the short precise directions for manipulations in the preparations of their galenicals. The explicit directions and unnecessary repetitions in our present U. S. P. could be well dismissed and given a place in the Dispositions or Commentaries. We will also be impressed with the physical description of galenicals in the foreign pharmacopoeias which should be adopted in the coming U. S. P. revision and serve as a guide to the practical dispensing pharmacist. Simplification should be practiced more extensively in the coming U. S. P. revision. Maximum single and daily doses are certainly an improvement over the average doses. The adoption of a distinctive sign, as an exclamation point (!) in case the maximum dose is exceeded in a prescription, would serve as a safeguard to both pharmacist and physician.

In conclusion I beg to thank the members who have so willingly offered themselves to take part in this symposium which I trust will be remembered for a long time to come, and also let me hope that such a symposium will be held in the Section on Practical Pharmacy and Dispensing in advance of every U. S. P. Convention. There is no doubt in my mind that the symposium will again prove what I have said on previous occasions, that the U. S. P. is peerless among the pharmacopoeias of the world or, as such an authority as the German pharmaceutical historian, Hermann Schelenz has so well expressed, "The U. S. P. is without doubt the aristocrat of all the pharmacopoeias."

On motion of Mr. Ladish, the paper was accepted, to take the usual course.

Mr. Raubenheimer resumed the chair.

The Chair called on Mr. Wilbert to read a paper on "International Standards" and Mr. Wilbert presented his subject as follows:

INTERNATIONAL STANDARDS.

THE RELATIVE COMPLIANCE OF VARIOUS PHARMACOPEIAS WITH THE PROTOCOL OF THE BRUSSELS CONFERENCE.

BY M. I. WILBERT.

It is quite probable that for far-reaching effect no effort to establish greater uniformity in the strength of pharmaceutical preparations has been as successful or has met with such really widespread acceptance as the protocol adopted by the "International Conference for the Unification of the Formulae of Potent Medicaments," held at Brussels, September 15–20, 1902.
Among the unexpected results it is gratifying to be able to point out that the provisions of this protocol have been practically adopted in toto by a majority of the nations represented, and also by at least several of the countries that were not represented at the Conference and therefore not bound by the resulting treaty signed at Brussels, November 29, 1906, by the diplomatic representatives of the several powers.

It is particularly gratifying to learn that the importance of establishing universal standards for potent medicaments was early recognized, and at least a year before the provisions of the Brussels Protocol were embodied in the pharmacopœia of any one of the signatory governments they were included, almost entire, in the Pharmacopœia of Mexico.

It would be altogether superfluous to review, at this time, the various steps which led up to the meeting of the International Conference, in Brussels, in 1902, as they are described at some length in a series of articles by the late Frederick Hoffman (Amer. Journ. Pharm., 1901, v. 73, pp. 315, 373, 431), while the report by Dr. Frederick B. Power, one of the delegates of the U. S. Government (Ibid., 1903, v. 75, pp. 1–13) gives the additional information necessary to bring the review down to the time of the convening of the Brussels Conference, and also includes a translation of the protocol as finally adopted.

As noted above, this protocol forms the basis of an Agreement between the United States and other Powers respecting the Unification of the Pharmacœial Formulas for Potent Drugs, signed at Brussels, November 29, 1906, and this agreement is available in the form of a publication issued by the U. S. Department of State as "Treaty Series No. 510."

In connection with the "Digest of Comments on the Pharmacopœia of the United States of America (Eighth Decennial Revision) and the National Formulary (Third Edition)," now being compiled in the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service, an attempt is being made to reflect accurately the degree of compliance in the several available national pharmacopœias with the provisions of the Brussels Conference Protocol. Such of our members as are interested in the more complete data are referred to the above publications.

For the present occasion an attempt has been made to illustrate, in a practical way, the changes that have been brought about during the short period of less than 5 years since the first national pharmacopœia issued for, or by any one of the signatory powers was published in 1905.

The conditions existing at the time of the convening of the Brussels Conference are fairly well reflected by Table I, while the now existing conditions are shown by Table II.

</table>
The Brussels Conference Protocol includes a total of 42 titles, of which 11 are simple substances and 31 galenical preparations. In the above tables an attempt has been made to present the former and the present drug strength of 22 of the more important of these preparations in accordance with a table originally compiled for the American Journal of Pharmacy (1903, v. 73, pp. 13–27; See also Proc. Am. Pharm. Ass., 1903, p. 571).

The tables are based on the minimum, permissible, active principle content of the drug or resulting preparation, wherever this is specified in the International Protocol. For this reason no cognizance is taken of the fact that many European Pharmacopoeias direct that tincture of opium be made by dissolving an assayed extract of opium in the required menstruum. It also explains the reason why the U. S. P. opium preparations are given as representing 12 per cent, in place of 10 per cent, of the drug.

The general status is perhaps even more graphically presented in Table III; showing the total number of drug-strength compliances, in the several pharmacopoeias enumerated, with the requirements of the International Protocol, in 1902 and in 1910.

**Table III.**
*Showing Total Number of Compliances and Non-Compliances with the Requirements of the International Protocol.*

Attention should be directed, specifically, to the fact that the appended
tables illustrate only the approximate compliance in the drug strength of the several preparations. In this one particular our U. S. P. grees fairly well with the international requirements aside from the use of the English practice of measuring in place of the continental practice of weighing the resulting liquid preparation.

Apart from this rudimentary requirement of per cent. of drug strength, however, the U. S. P. VIII differs more widely from the actual requirements of the Brussels Conference Protocol than any one of the other national pharmacopoeias. In the light of what has actually been accomplished, it appears to have been unfortunate indeed that pharmacists in this, the most cosmopolitan, and in many respects the most advanced, country of the world, were not sufficiently alive to the possibilities that presented themselves in this connection, to insist that the proposed international standards be adopted in their entirety seven years ago when the present revision of our pharmacopoeia was in press.

It is probable that no one feature of the U. S. P. VIII has been more severely criticised abroad than the failure to comply more fully with the provisions of the Brussels Protocol, and our failure to live up to these requirements has no doubt influenced at least some of the committees or commissions revising the pharmacopoeias of other countries and prevented a more complete compliance on their part. Thus it has been pointed out by Greenish and others that of the first national pharmacopoeias to be published after the signing of the Protocol at Brussels, in 1902, the Spanish Pharmacopoeia leads by conforming to 96 per cent. of the requirements; the Belgium Pharmacopoeia conforms to 87 per cent., the Dutch Pharmacopoeia 81 per cent., the Austrian Pharmacopoeia 77 per cent., and the Pharmacopoeia of the United States to but 27 per cent. of these requirements. To arrive at these results Belgium was compelled to modify 80 per cent. of the formulas, Spain 75 per cent., Holland 39 per cent., and Austria but 6 per cent. of the corresponding formulae contained in the previous editions. Henry G. Greenish (Pharm. Jour., June, 1907, p. 832) in further discussing the same question makes the following comment: "The conspicuous failure on the part of the United States to bring its formulas into harmony with those of the agreement, as shown by the table, and also the notes on the various preparations, is the more remarkable when considered in conjunction with the statement in the preface (of the U. S. P.) that 'the recommendations of this (the International) Conference have been adopted by the Committee of Revision except in one or two instances.'"

The more evident variations are in the nomenclature of the official substances, the strength of menstruum, and the general non-compliance with articles 2 and 3 of the Protocol. The variation in nomenclature is perhaps the most unfortunate shortcoming, for it is generally acknowledged that multiplicity of names or multiplicity of applications for the same
name must lead to confusion, and confusion is and ever has been a bar to progress.

In a paper on the then newly-proposed international standard tinctures of potent remedies (Am. J. Pharm., 1903, v. 75, pp. 20-27) I ventured the opinion that: The advantage that must be admitted in favor of the proposed international standard menstruum is that it would be uniform in strength for all extractive tinctures of potent drugs; that the keeping qualities of the preparations would be improved; that a smaller proportion of the inert materials would be extracted, and that therefore less precipitation would take place.

The opinions expressed at that time have been amply verified in practice. With the single exception of tincture of ipecac, international standard tinctures made more than seven years ago are still clear and evidently satisfactory, while corresponding preparations made with the U. S. P. VII menstruum of diluted alcohol generally precipitated heavily within a few years at most.

One perhaps important feature in this connection is that approximately 70 per cent. alcohol has long been recognized as being a much more efficient antiseptic than either more dilute or more concentrated mixtures of alcohol with water. This one property of 70 per cent. alcohol alone should warrant its careful consideration on the part of the next U. S. P. Committee of Revision for adoption as a routine menstruum in place of the diluted alcohol now generally prescribed.

For the sake of international uniformity this strength of alcohol should certainly be used in connection with tinctures of potent drugs when specified in the Protocol of the Brussels Conference.

The provisions of articles 2 and 3 of this protocol are also well worth endorsing in their entirety.

The provision that no extractive preparation of a potent drug be directed to be prepared in the form of a medicinal wine is a reasonable one, in view of the variation in alcohol strength of and material held in solution by wines of different origin.

The adoption of a normal drop measure can now hardly be objected to in view of the general acceptation of this provision in the pharmacopoeias of foreign countries.

Altogether it would appear that in view of the widespread and general acceptation of the provisions of the "International Agreement respecting the Unification of the Pharmacopoeial Formulas for Potent Drugs" by the powers signatory to the treaty of 1906, the Pharmacopoeia of the United States of America should surely be made to comply with the letter as well as with the spirit of that agreement.

It would also appear desirable that in future we should endeavor to lead in matters relating to the establishment of greater uniformity in the standards for widely used drug products and thus evidence our desire or
at least willingness to take an active part in promoting the sciences relating to the preparation and the use of drugs for the prevention and cure of diseases.

The Chair said this was very valuable work that Mr. Wilbert had done, and was right along his line—that he liked to do it, and he hoped it would be appreciated. He invited discussion upon the paper, but none was offered.

The next item upon the program was the Austrian Pharmacopoeia. This was verbally reviewed at some length by the Chairman himself, who asked Associate White to preside for the time being.

The Chair invited discussion.

Mr. Wilbert exhibited the German translation of the Austrian Pharmacopoeia to the members, and referred to the limitation for age of drugs contained therein. This he said was a common feature of European Pharmacopoeias. He spoke of Rhamnus purshiana being several years old prior to coming to Austria, and also commented upon the fact that aconite did not appear in the Austrian Pharmacopoeia, as an illustration of the old saying that a prophet is not without honor save in his own country. Aconite, he said, was introduced into medicine in Austria in the eighteenth century, and was introduced from there into other countries, and yet aconite had entirely disappeared from the Austrian Pharmacopoeia. Another interesting feature of the Austrian Pharmacopoeia was the use of the name acetphenetidin for phenacetin.

Mr. Raubenheimer, in regard to Rhamus purshiana, stated it might be true that it was a year old before it came to Austria, but he thought the U. S. P. made it two years old.

Mr. Day suggested that it was one year in the U. S. P.

Mr. Hallberg said that the manufacturers usually let it lie about four years.

On motion of Mr. Ladish, the paper was received and ordered to take the usual course.

Mr. Raubenheimer resumed the chair, and called for the reading of a paper on the Belgian Pharmacopoeia, by Mr. Motter. The author had to return to Washington City, he said, and he asked Mr. Wilbert to read the paper.

PHARMACOPEIA BELGICA III.

BY MURRAY GALT MOTTER, WASHINGTON, D. C.

In response to our Chairman's invitation, I have undertaken a brief review of the current edition of the Belgian Pharmacopoeia, which will consist of a very free paraphrasing of its preface, together with certain observations based upon comments encountered in our compilation of the data for the bulletins issued by the Hygienic Laboratory.

The third edition of the "Pharmacopoeia Belgica" was issued from
Brussels in 1906. To the preceding edition, published in 1885, there were added two supplements, the one in 1892 and the other in 1895. The third edition is printed both in Latin and in French. The work of revision was, by a royal decree dated October 13, 1897, assigned to a commission consisting of two physicians and five pharmacists (two of them inspectors), with Mm. Nelis and Ranwez, both of them pharmacists, designated as president and secretary, respectively. As a preliminary to the work of the Commission, the government sought the opinions of provincial medical commissions with reference to the modifications to be introduced into the pharmacopoeia; while, in the course of its work, the Commission communicated its provisional results to the medical and pharmaceutical societies, inviting comment thereon. It is interesting to note, in this connection, that the statistics furnished by the inspection service of the country had long since demonstrated the need of further and more precise definition of analytical methods and processes.

In the matter of admissions and eliminations, practical usage and real utility were adopted as the guiding principles.

For simple drugs, the precise designation of the botanical species and part of the plant used, while for powders, tinctures, extracts and certain other products, the assay processes furnish data sufficient to establish the quality of the drug.

In the case of balsams, gum-resins, essences, oils, fats, waxes, etc. assays are prescribed which provide for the detection of the more common adulterants.

With reference to galenicals, which it is assumed that the pharmacist himself is able to prepare, certain quantitative determinations are prescribed; an ash content for powders, a dry residue for tinctures and fluidextracts and, wherever practicable, the active principle content.

Especially in the case of the natural drugs which constitute the "heroic medicaments," such as opium, nux vomica, belladonna leaves, etc., where, owing to the very variable content of active principles it is otherwise impossible to secure preparations of uniform strength, the pharmacopoeia prescribes well-defined assay processes for these active substances, which are to be isolated and standardized. It was, of course, to be expected that the Belgian pharmacopoeia would show a close adherence to the decisions of the Brussels Conference for the Unification of Heroic Medicaments.

A number of fluidextracts were adopted for the extemporaneous preparation of certain medicaments. In the matter of simple vehicles and excipients considerable latitude is allowed; thus, no particular wine is specified, but any wine conforming to certain general qualities is permitted. The same general principle is followed in the preparation of medicinal oils, capsules, perles, etc.

Chemical medicaments are, with rare exception, the products furnished
by commerce, but "purity rubrics" have been notably developed. Assay processes are given with considerable attention to detail, as to conditions of operation and quantities entering into reaction. For the calculation of solutions and analytical determinations, atomic weights are given in round numbers.

This pharmacopoeia includes certain formulas for veterinary preparations, with the view that all such medicaments should respond to the same tests, as to purity and strength, as in the case of medicines intended for mankind.

Save where there is special indication to the contrary, certain general rules are to be observed:

Natural drugs (organs and plants) are to be employed in the dry state. All quantities indicated by the term "parts" are parts by weight.

Temperature indications refer to the Centigrade thermometer.

Pharmaceutic operations are undertaken at ordinary temperatures, in neighborhood of 15° C.

Analytic determinations, unless otherwise specifically mentioned, are to be made at 15° C.

The water employed is always distilled water, conforming to the title Aqua, for which the synonym is Aqua destillata.

The concentration of solutions is indicated by the relation between the weight of the substance dissolved and that of the solution obtained. For example, the aqueous solution of potassium bromide 1:10 is prepared by dissolving 1 Gm. of potassium bromide in 9 Gm. of water, which yields a total of 10 Gm. of solution.

When a solution is mentioned without indication as to the solvent, an aqueous solution is meant.

In the assay of medicaments, the name of a reagent designates the product described in the list of reagents.

When, in any preparation, the pharmacopoeia prescribes a minimum of a particular principle, this prescription is to be taken in a strict sense, and any medicament which contains a lesser proportion of the principle should be rejected.

If there be prescribed a determinate content of any special constituent, without special indication that this proportion constitutes a maximum or a minimum, the figure given is understood to be not incompatible with slight differences inherent in the preparation of the product and in the method of analysis.

When the pharmacopoeia provides a medicament in diverse states of concentration, the simple mention of the medicament refers to the product designated by the corresponding title. Thus, the pharmacopoeia describes hydrochloric acid in two states of concentration: Acidum chlorhydricum, containing 36.5 per cent., and Acidum chlorhydricum dilutum, containing 7.3 per cent. of hydrochloric acid gas: if "Hydrochloric acid"
be prescribed, without anything further, the medicament described under the rubric *Acidum chlorhydricum* is to be used. The dilute acid should never be employed unless specifically designated in the prescription.

The pharmacopoeia is divided into two parts: the first, devoted to the description of the medicaments, their preparation and analysis; the second part contains the provisions relating to reagents, the description of certain analytic processes, a series of alcholimetric tables, the chemical formulas and the solubilities of a number of medicaments.

This comprises, among other things, a series of lists established in the enforcement of the laws and regulations:

(a) List of obligatory apparatus.
(b) List of obligatory medicaments.
(c) List of medicaments to be kept from air and light.
(d) List of heroic medicaments.
(e) Table of maximal doses.

Some of these lists should give us pause. Imagine, for instance, the furore which would be raised among some of our happy-go-lucky druggists, of free-and-easy equipment and unmentionable preparation, were some enterprising State legislature to pass a law requiring every pharmacy to be equipped with a microscope, with burettes and pipettes graduated to \( \frac{1}{10} \) Cc., a balance to weigh accurately between a kilogram and a decigram, and another, sensitive to at least a milligram. Imagine, too, what some of the brethren would do with such an equipment if they had it! Think of the welcome which would be accorded the official inspector who would be required to certify that you had in stock, at any old time, not only a specified amount of each of a list of upwards of 500 medicaments, but that they were of pharmacopoeial standard, then and there determined with official apparatus and solutions likewise required to be at hand.

There is also included in this second part a table of names and synonyms in which the pharmacopoeial titles are designated by an asterisk, and the titles of those substances, the composition of which is regulated by the Brussels Conference, are printed in fat-faced type.

Coming now to the main portion of the book, the first part, we find a total of 722 titles: 22 general formulas and descriptions, 17 animal drugs, 168 vegetable drugs, 173 chemicals, 329 preparations, and 3 cross references.

As to classification, the alphabetic order, under the Latin titles, is preserved. Wulff (Ber. d. phar. Gesellsch., Berl., 1906, v. 16, pp. 251-264) notes that this order permits all of the preparations to appear alphabetically with the drug itself. But the inconvenience of a too rigid and mechanical adherence to such an order is seen, for instance, in the interpolation of *Acidi citri syrupus*, *Acidi tannici glyceritum*, *Acidum aceticum*, *Acidum aceticium dilutum* and *Acidum benzoicum*, between *Acidi boricum unguentum* and *Acidum boricum*.
It has also been a matter of comment that while the international agreement has been followed as to titles, requirements and formulas, the latter are not specifically designated in the text, either by the initials F. I. (formula internationalis) or by some special typographic sign. The now obsolete nomenclature of Acidum carbolicum is retained in the title, though the synonyms Acide phénique and Acidum phénicum are given.

Among the accepted titles we find antipyrine and phenacetin, while such terms as aristol, dermatol, diuretin, etc., appear as synonyms for the respective compounds. The synonyms, by the way, are confined almost exclusively to the French text. There is, too, rather an inordinate number of homonyms; while we may have been brought up on Fowler's solution or Sydenham's laudanum, van Swieten's solution, de Haen's pills and Helmerich's pomade make one sigh for a saner nomenclature, based upon international agreement.

Serum Antidiphthericum and Serum Antitetanicum were introduced, though without any indication as to standards. Since 1906, it is understood, the Ehrlich standard has been adopted for the former; as to the latter, a standard has been perfected in the Hygienic Laboratory, U. S. Public Health and Marine Hospital Service, and the director of this laboratory was advised, under date of March 24, 1910, of its endorsement by the Belgian government, the writer of this official notification paying high tribute to the excellence of the American standard.

For Tuberculinum there is no standard, though the method of preparation is stated. Vaccinum is to be prepared by an official commission at the central vaccine institute, connected with the school of veterinary medicine of Brussels-Cureghem.

The details as to compliance with the protocol of the Brussels Conference, have been compiled by my friend and colleague, Mr. M. I. Wilbert and will be presented in another paper before this section.

On the whole, one may well wish that the makers of the United States Pharmacopoeia might emulate their European cousins in looking upon the Pharmacopoeia rather as a scientific work, for the protection of the general public, than as a book of more or less commercial standards, compiled in behalf and at the behest of trades' or merely professional interests.

Mr. Eliel said he took exception as a pharmacist to the statement contained in the paper about the conditions found in drug-stores in this country, and expressed the opinion that if the conditions prevailing in Continental countries as to inspection applied in this country, there would be no ground for the criticism. Referring to the claim of commercialism he had heard made against American Pharmacy, he said he did not know of anything that was on a more thoroughly commercial basis in this country to-day than the practice of medicine. In the U. S. P. and N. F., great stress was laid by physicians on requiring the elimination of therapeutic titles. As a matter of fact, neither the U. S. P. nor the N. F. con-
tained one-tenth as many therapeutic titles as the German, Belgian, Austrian and other Pharmacopoeias of other countries, where the practice of medicine was on a very much higher plane than it was in this country.

The Chair said that no doubt Mr. Eliel was right in this respect, but he thought Mr. Motter was evidently not considering such pharmacists as Mr. Eliel when he made the statement objected to. Continuing, the Chair stated that he thought Mr. Motter's paper showed that the pharmacists of this country would have to be very careful in compounding foreign prescriptions, because, as he had pointed out as to the Austrian Pharmacopoeia, acetic acid, for instance, was diluted to the greatest extent in that country, whereas in the Belgian it was the most concentrated.

At the request of the Chair, Mr. Dunning then proceeded to read a paper upon the French Pharmacopoeia, or "Codex."

REVIEW OF THE FRENCH CODEX.

The present revised edition of the French Codex went into effect Sept. 15, 1908. It is a volume containing 1,023 pages, printed in the French language; Latin names are used as synonyms for titles of drugs appearing therein.

The subject-matter is discussed under a number of headings. First appears the report to the president of the French Republic by commission appointed to revise the previous edition. This report includes a statement regarding the character of the previous edition, and the authority for and composition of the commission having the present revision in charge.

In all the Commission was composed of sixteen original members, four being medical men, eight pharmaceutical; other members were the director of higher education, who acted as president, a professor in a Veterinary School, director of Pasteur Institute and one other connected with the department of education. During the existence of the Commission five members were deceased, three were replaced by pharmacists and two from the department of education. The official sanction to the publication of the Codex is requested of the President.

The degree of the President comes next in order which consists principally of a statement in regard to his acceptance of the Commission's report and the attachment of his official signature.

Most interesting is the vast amount of work necessitated by the following program of revision; 913 preparations were dismissed, 575 galenicals, 210 drugs, 98 chemicals and 30 veterinary preparations; 154 preparations were added, and 131 old formulas revised.

The present Codex contains 1,125 monographs, chemicals 291, drugs 290, galenicals 429, surgical dressings 7, descriptions of powdered drugs 27, general descriptions 46, veterinary preparations 27 sera and vaccines 8. These include formulas for medicated baths, fumigations, gargles, mustard foot-baths, 48 teas, 51 syrups, specific gravity and percentage tables,
refractive indices for several volatile oils, also optical rotation, in some cases, for solutions of chemicals.

New remedies are included under the scientific chemical name.

Chapter on physiological preparations, general information respecting extracts from animal organism, intended for injections, sera and vaccines, including diphtheria antitoxin, antipest serum, antistreptococcus serum, antitetanus serum and antivenom serum, tubercular and antipest vaccines.

Veterinary preparations, 17 articles including description of mallein and tuberculin.

Appendices.

List of toxic drugs, kept under lock and key, name in black on orange-red ground; list of drugs to be kept from others, black on green labels.

Terms of Brussels convention.

Table of atomic weights.

Drop table.

Chapter on various methods of determining specific gravity.

Alcohol table.

Reagents and volumetric solutions.

List of omissions, additions and alterations.

Table of maximum doses.

Extracts from laws and regulations affecting the exercise of the pharmaceutical profession and relating to pharmaceutical studies.

General index.

With some necessary exceptions the Commission conform to the decision of the Brussels Conference in regard to the formulas for heroic remedies, which necessitated changing the strength of a number of the preparations; of particular interest being the increase in strength of tincture of ignatia 2 1/2 times.

The older order and system of classification of medicines is entirely reconstructed. The principal classes are "simple drugs of animal or vegetable origin;" "chemicals and galenicals" are together, alphabetically arranged. The other drugs are included under physiological preparations, which are further subdivided, and veterinary medicines.

Regarding the tests an innovation is practiced, in that tests for impurities are given in smaller type, while the impurity to be detected appears in parentheses and in italics.

The employment of the polariscope as a means of testing is mentioned not only in connection with its use in assaying volatile oils, but also with certain alkaloids and other substances.

Under the heading "Mode of Employment" are given the official preparations in which the particular substance appears and has no reference to therapeutic use.

In the discussion of those substances which are poisonous, the relative terms tres toxique, toxique and "a separer" occur in heavy black type.
Referring to the chemicals, which appear in the principal division of the book as before stated, the acids appear in alphabetical order in accordance with the name of the acid; for instance, acetic acid, chlorhydric acid, etc., while the metallic compounds and alkaloids are arranged according to a like provision, calcium sulphate, etc.

Molecular, empirical and constitutional formulas are given.

Each substance is described in the following order:
Name in French (the principal title), Latin name.
b. Formulas.
c. Preparation.
d. Physical and chemical characteristics, special properties.
e. Tests of identity and purity and for impurities.
f. Dosage (that is assay).
g. Conservation.
h. Incompatibilities.
i. Mode of employment.

Method of preparation of medicinal chemicals or active principles are not given when they may be obtained in commerce in a pure state, but when these substances may vary in accordance with the method, then formulas are given.

In this connection, I desire to remark that the number of chemicals for which the Codex gives processes for preparing are far in excess of those appearing in the U. S. P.; as example may be mentioned scale salts of iron, arsenate of iron and many other such as would be of no value in our own Pharmacopoeia.

In regard to drugs which were included in the previous Codex but few were accompanied by proper definition and description nor were methods of standardization and assaying chemicals or galenicals included. These methods or processes are introduced into the present Codex in much larger numbers and are far more extensive and comprehensive than in the U. S. P.

It appears to me that in some instances extravagantly comprehensive might be applied.

The revised Codex now contains a special article for each substance discussed although general processes are referred to whenever such seem applicable.

In my opinion one of the most important improvements.

The maximum doses of drugs, which are not to be exceeded except in special instances, are given in a table in one of the appendices. This I believe to be a good feature, inasmuch as the term maximum may be defined as meaning dose sufficiently large to question. In case the physician desires to direct a larger dose than the so-called maximum he indicates his intention by the words “re dis” which is equivalent to “O. K” in America.
It is my intention to conclude this brief review with equally brief or briefer comments on some of the substances, either as classes or individually, which appear in the principal part of the book.

The general character of the contents of the French Codex differs widely from that of the United States Pharmacopoeia, particularly as regards the type of some of the preparations, notably, teas, medicated baths, fumigations, gargles, foot-baths, etc., and furthermore many drugs the medicinal value of which the U. S. P. committee would not consider of sufficient importance to recognize, but are found in our Dispensatories as one of the many.

In fact the French Codex, in many respects, more closely resembles an American Dispensatory than the American or rather the United States Pharmacopoeia. As an illustration of this point may be mentioned the full information offered in regard to many physical and chemical characteristics of substances which are not required for the purpose of standardization; under acetic acid for instance, I note the following: "It dissolves camphor, the resins, etc. Under the same heading a discussion regarding the relation between the density of acetic acid and its strength is incorporated.

No assay methods are directed for the drugs proper, aconite, belladonna, etc., but for their preparations.

Now referring to the several classes of galenical preparations:

Alcoolats are substances, simple or compound, prepared by macerating with alcohol of varying strength and then distilling.

Alcoolatures are prepared by macerating the substance with 80 or 95 per cent. alcohol and expressing.

Hydrolats correspond in some respects to our aromatic waters but are prepared by macerating the drug with water and subsequently distilling. Peppermint water is so prepared.

Some of these preparations remind one of Warburg’s Tincture containing from 16 to 19 ingredients, Electuarium Diascordium being a fair example.

Six elixirs are recognized; they do not resemble the American elixirs, so much as they do the wines. They vary greatly in alcoholic strength ranging from about 60 per cent. in Elixir paregorique, while Elixir garu contains about 40 per cent. and enough sugar to make a fairly heavy syrup, Elixir cocoa is very weak in alcohol and contains but little sugar, and Elixir of Pepsin is more a wine than an Elixir.

The plasters seem to be more complex than necessary. Adhesive plaster contains eight ingredients, diachylon plaster nine, and mercury plaster eleven.

Three emulsions are included in the Codex—emulsion of sweet almonds, coal tar and cod-liver oil. Coal-tar emulsion is a soap bark alcoholic solution of coal tar mixed with water. Cod liver oil is emulsified with a hot solution of Irish moss.
Sponge and aseptic sponge are recognized. Several species are also included, one of which contains a combination of 17 leaves and flowers.

Eighteen essences (volatile oils) are recognized. Bergamot, cinnamon, cloves, lavender, santal, thyme, are accompanied by assay processes, most of the others by special tests for identity and purity; all are accompanied by tests for characteristic properties and some few are directed to be examined with the polariscope.

The extracts are divided into four classes; fluid extracts correspond in strength to weight of drug employed.

Soft extracts having the consistency of honey, firm extracts and powdered extracts.

Drug is prepared in each instance by moistening, then macerating for ten hours, packing in percolator, covering with menstruum, which is allowed to percolate until it commences to drop, when the orifice is closed and the drug is further macerated for 24 hours.

All the extracts containing alkaloids are directed to be assayed. Tests of identity are included for many others.

These assay processes differ considerably in detail from those of the U. S. P. Regarding the efficiency of these processes, I shall not attempt to pass judgment or make comparison to any great extent. In the assay of opium the drug is mixed with lime and extracted, no alcohol is used in connection with the assay.

There are 44 of these extracts, eleven of them are fluid, only the soft extract of digitalis, powdered extract of nux vomica, aconite and belladonna are recognized.

Aconite and belladonna assays are probably more tedious than the corresponding methods of the U. S. P.

Fumigating formulas are included which are combinations of chemicals for liberating chlorine; and sulphur in form for burning; four formulas for gargles and four for medicated gauze, four for honeys.

OINTMENTS.

Lard, benzoinated lard and vaseline are the bases directed for ointments. They resemble in character of the formulas the ointments of the U. S. P.

One rather interesting ointment is that of chloroform 10 per cent. in white wax and lard.

A much larger number of ointments is recognized in the Codex than in the U. S. P.

The yellow oxide of mercury ointment is directed to be prepared with vaseline, which I believe to be an excellent base for this purpose. Oxide of zinc ointment is prepared in vaseline 10 per cent. Mercurial ointment is prepared with lard. The Codex includes an ointment of salol.

Several potions of questionable value are included in the Codex.
The French Codex syrups are of a character distinctively different from those of the U. S. P.

Syrup of aconite, tincture of aconite and syrup; syrup of potassium bromide, syrup of morphine; syrup of codeine; syrup of digitalis, tincture digitalis and syrup; syrup iodide of mercury, potassium iodide, mercury biniodide, water and syrup and many more of like character are included under this heading.

There are fifty syrups; quite a few are accompanied by tests when the character of contents would indicate the necessity of.

Some of the syrups are prepared by heating the principal constituent with the simple syrup on a water bath and subsequently filtering. Syrup of tolu is prepared by heating tolu with water for two hours on a water bath with frequent agitation, filtering and dissolving sugar in filtrate.

The simple syrup is not a saturated solution of sugar, most others being more or less saturated with sugar.

TINCTURES.

There are fifty-five tinctures recognized.

These tinctures are prepared by maceration, simple solution or by percolation, the latter process being used only with those tinctures which conform to the requirements of the Brussels Conference. The alcoholic strength of these preparations ranges from 60 to 95 per cent.

Tinctures of potent drugs are prepared by percolation with 70 per cent. alcohol as the menstruum, and of strength ten times greater than the drug employed.

Tincture formulas are accompanied by description of physical characteristics, tests of identity of finished preparation, and those which are assayable are accompanied by assay processes.

The Chair exhibited a volume of the French Codex, and spoke of its poor binding. He also called attention to the French labels for external use—red, printed in black.

Mr. Wilbert also explained the arrangement of the Codex, and compared the present edition with the Codex of 1884, and said it contained upward of 640 less titles. In France, an article not embraced in the present Codex was considered official if it appeared in the previous edition, as the Attorney General had decreed that an article found in the former Codex was quite as official as one in the present volume. On the strength of that decision they had reduced the number of titles very considerably. He said the polypharmacal preparations were more fully represented in the French Codex than any other pharmacopoeia.

Mr. Hallberg said that the former Pharmacopoeia had the tri-color—red, white and blue. He said that whenever a preparation seemed to be used sufficiently to warrant it, it was included in the Codex. He thought
the system prevailing there had contributed to a more scientific class of proprietaries in France than in this country.

The Chair called attention to the fact that the commission to revise the Codex seemed to be largely composed of pharmacists. He went on to say that the third edition of the Codex was published in 1886, the fourth in 1894, and the fifth edition in 1908. As to the polypharmaceutical preparations spoken of, he said that, whereas the edition of 1866 contained 99 such preparations, the fourth edition, published in 1894, contained only 56, and the new Codex contained none at all.

Mr. White asked Mr. Dunning if there was any reference in the French Codex to a class of preparations known as "ampoules," and Mr. Dunning replied in the negative.

Mr. Dunning stated that the French Codex, in the matter of description of chemicals and drugs, reminded him much more of the American Dispensatories than it did of the United States Pharmacopoeia. He disclaimed that in so saying he meant to say anything derogatory to the Dispensatories.

The Chair stated that the German Pharmacopoeia was the next item on the program, but that, in the absence of the author, Mr. Goetting, he himself would give a short abstract of it. This he proceeded to do, the full text of the paper being as follows:

**SOME REMARKS ON THE GERMAN PHARMACOPOEIA.**

*BY E. C. GOETTING.*

**INTRODUCTORY.**

A pharmacopoeia is in my opinion not a book for study but a law book, written for the purpose, to be a guide for physicians and druggists and manufacturers. In order to fulfill this purpose, it must not be too voluminous and complicated, the wording should be plain and the demands in regard to purity of chemicals and strength of drugs and preparations should be precise and distinct. It is an undisputed fact, that too rigid laws are bad laws, that they always become unpopular and therefore cannot be properly enforced. For this reason it seems to be advisable, that the revisers of a pharmacopoeia in their demands should not be narrow-minded and unduly scrupulous in regard to the purity of chemicals and drugs, by which the price of medicines might be unnecessarily increased and the jobbers and retailers be tempted to try to evade the stipulations of the law.

**HOW THE GERMAN PHARMACOPOEIA IS REVISED.**

The revision of the German Pharmacopoeia is entrusted to a stationary commission, headed by the director of the Health Department, (Kaiserlichen Gesundheits Amt). The commission consists of members of the department and 18 or more delegates of the medical faculties, experts of
serum therapeutic practices, chemistry, pharmacognosy and pharmacy and also members of the veterinary schools. All of these are appointed by the German Chancellor. This Commission has to keep in touch with the advance of pharmacy and medicine and must report every two years to the Chancellor all changes, which they deem advisable to be made in the Pharmacopœia. In order to have the report complete and embracing all parts of the empire the Commission requests the owners of large pharmacies in cities and country, to forward their individual opinion in regard to the omission of older remedies and the incorporation of new ones.

All this material together with the recommendations gathered from articles in the pharmaceutical journals is systematically arranged and put before the Commission, who after agreeing as to which new remedies should appear in the new edition of the Pharmacopœia, place the whole material before the members of the pharmaceutical committee for revision and approval. This report is sent to each member of the Commission and when the whole Commission soon meets again and its members have agreed upon the contents of the Pharmacopœia and have decided in regard to the quality of drugs, chemicals and the most desirable preparations therefrom and the methods making them, the whole work is finally approved by the Health Department and ordered to become a law.

THE TEXT OF THE PHARMACOPEIA.

When we take the German Pharmacopœia at hand, we notice, that it is decidedly less voluminous than the U. S. P., not in regard to the number of drugs and preparations but mainly in regard to the description of manipulations for making preparations and methods to ascertain identity and purity of chemicals.

I am of the opinion that this is a decided advantage. The text is short and distinct, and anything not necessary for the purpose has been avoided. The formulas seem to be arranged better and more practically for laboratory work. There are no repetitions, while in the U. S. P. the process of maceration and percolation is repeated at every tincture and fluidextract. The revisers of the German Pharmacopœia seem to have more confidence in the practical education and experience of the druggist, as they do not consider it necessary to minutely describe the modus operandi at each preparation.

FLUIDEXTRACTS.

Fluidextracts are not very much favored in Germany, but I do not doubt that in the next edition more fluidextracts will be found. They are without doubt very useful preparations for the pharmacist as well as for the physician.

TINCTURES.

According to the German Pharmacopœia all tinctures are made by maceration. This has been the custom in Germany for years and as even
here in our country, where all tinctures are percolated, practical men claim, that for the preparation of tinctures maceration is preferable, a change in the German Pharmacopœia in regard to tincture is not to be expected. There is no doubt that percolation has its advantages, as well as disadvantages, but nobody will dispute that the quality of a tincture to be made by percolation depends mostly on the practical experience and training of the man in the laboratory.

SYRUPS.

The German Pharmacopœia orders the syrups to be made from the herb directly, with the addition of a little alcohol to the menstruum. Most of the alcohol will evaporate when the sugar is dissolved by heat; the addition of some glycerin therefore would be advisable to prevent fermentation. The U. S. P. syrups are made with fluidextracts. They are much stronger and some of them contain enough alcohol to prevent fermentation, while others could be improved by the addition of glycerin.

OINTMENTS.

The German Pharmacopœia provides for all ointments a base, which will not get rancid. Also the U. S. P. seems to favor the petroleum base and woolfat, but some ointments, Ungt. Gallae., Ungt. Belladonae, etc. have to be made with a base, which gets rancid and lumpy very soon. This ought to be changed.

ASSAYS.

The German Pharmacopœia demands in comparison with the U. S. P. a few assays only. This seems to be a disadvantage, but when we consider, that according to high authority the methods for some of these assays are not reliable, it is perhaps wiser to omit them than to bulk the Pharmacopœia with tests, by which the strength of a preparation cannot be ascertained with absolute security.

REAGENTS.

We find the formulas for reagents and volumetric solutions in the German Pharmacopœia on 12 pages, while the U. S. P. 50 pages are devoted to the same subject. This is decidedly unnecessary. Some of the formulas can be given in shorter terms and others, f. i. those for special tests and Vol. Sol. belong in a text-book of chemistry and not in the Pharmacopœia.

TABLES.

The German Pharmacopœia has only a few tables, one of which, the dose table, can be omitted, as all the doses have been stated in the respective paragraphs. Some of the tables in the U. S. P. VIII are quite useful, others again might just as well be omitted, as they are hardly ever used.
Much more could be said in regard to the subject, but as the article is not intended to touch details, I will come to a close. Only one more point I wish to bring out, that is to warn the Committee of Revision of all Pharmacopoeias, to avoid in the formulas of preparations such changes, by which color and taste of the article is impaired. Any such changes for obvious reasons should be made only when they are absolutely necessary.

_N. Y. City, April, 1910._

Mr. Hallberg remarked that this was the only one of the Pharmacopoeias that was not called "Pharmacopoeia."

A paper on the Pharmacopoeia of Great Britain, by E. H. Gane, was, in the absence of the writer, read by title and referred:

_A COMPARISON OF THE BRITISH AND U. S PHARMACOPEIAS._

_BY E. H. GANE, NEW YORK CITY._

The current British Pharmacopoeia issued in 1898 was notable from the fact that for the first time pharmacists were invited to aid in its revision. The British Pharmacopoeia is published by the General Medical Council of the United Kingdom under Act of Parliament and the Council has always been exceedingly jealous of its prerogatives. Consequently, while a formal invitation was sent to the Pharmaceutical Society of Great Britain inviting its cooperation, the committee appointed in response to the suggestion had no real power and its recommendations were at all times subject to the veto of the General Medical Council. The position of the committee was a rather anomalous one and many pharmacists thought that the Society would have done better to have declined to act under any such conditions. The published book, however, bears evidence of the fact that the Pharmaceutical Society's committee of practical pharmacists had a great deal to do with improving the character of the British Pharmacopoeia, for no such volume of criticism greeted the 1898 revision as was aroused by the 1885 issue.

The above brief mention of conditions is made for the purpose of explaining why certain sharp points of difference are noticeable between the British and the U. S. Pharmacopoeias.

It is impossible in the limits of a brief review to point out all the important features of the B. P. even if it were desirable to do so. It would seem that the most useful purpose of a series of papers such as we are having presented, would be served by pointing out the principal points of difference between the two books, with the ultimate idea of obtaining in all countries a uniform standard of medicinal products so that no matter where a patient may find himself, he can be reasonably sure of getting a prescription dispensed in uniform manner. This should be the desire of Pharmacopoeia revisers the world over.

For the purpose of this discussion it seems best to briefly note the general
characters of the British Pharmacopœia and then devote our attention to
the differences in strength and composition of the products common to
the two Pharmacopœias.

NOMENCLATURE.

Little comment is required in this connection. As might be expected
the Latin titles of botanicals and galenicals are rather more accurate in
the B. P. while the U. S. P. is more up to date in the use of chemical
terms. We do not find any such monstrosities as “Carbonemi and Fluidex-
tractum” in the B. P. and again we find some instances where the British
titles are more accurate than our own. For instance “Aqua ammoniæ”
and “Aqua hydrogenii dioxidi” are more accurately designated as
“Liquores.” Botanicals are designated more accurately by appending the
part used as “Acacie gummi” in place of “Acacia,” “Digitalis folia,”
“Conii fructus,” “Cinchonæ cortex,” “Ipecacuanhæ radix,” etc. “Cary-
ophyllus” is “Caryophyllum” in British eyes, “Fel bovis” is “Fel
bovinum” and “Glandulæ Thryoidæ siccæ” is simplified into
“Thryoidæum siccum,” “Petrolatum” is “Paraffinum,” “durum,”
“molle” or “liquidum” according to variety and “Paregoric” is “Tinc-
tura Camphoræ composita.”

The Englishman’s conservatism is displayed in the continued use of
“Acidum carbolicum,” “Soda Tartarata” “Potassa Caustica” and “Sul-
phocarbolas.” Both pharmacopœias continue the use of the well under-
stood but inaccurate “Liquor Calcis” and both append “Solution of Cal-
cium hydroxide” as the English equivalent though the British preface
states that the English title is not to be taken as a translation of the Latin.
Many of these differences will probably be adjusted in subsequent revisions.

BOTANY AND PHARMACOGNOSY.

The botanical names of the British Pharmacopœia, differ in some in-
stances from those of the U. S. P. and this is due to the fact that the names
in the British Pharmacopœia have been brought into accordance with the
“Index Kewensis.” The wording of the descriptions and characters of
the various drugs was carefully done so as to limit the quality to be used.
In the case of some twenty drugs ash limits were set to aid in detecting
adulterations.

CHEMISTRY.

The chemistry of the British Pharmacopœia has been so fully dealt with
that further comment at this time is hardly necessary. The principal fact
which aroused comment was the indefinite character of the test for impuri-

ities in chemicals. Instead of placing limits on the impurities allowable
the text says that a solution (strength not stated) “should yield no char-
acteristic reaction with the tests for lead, copper, arsenic, iron etc. or “not
more than the slightest characteristic reactions with the tests” for certain
impurities. In this respect the limits of impurity designated in the U. S. P. are a great step in advance. Processes for making chemicals were generally dropped from the last revision and in spite of the indefinite character of the tests mentioned above the chemistry of the British Pharmacopæia was a distinct advance over previous editions. As with our own Pharmacopæia the tests for certain chemicals were regarded as too stringent, inasmuch as the required condition of purity was not obtainable on the commercial scale without too great a cost.

WEIGHTS AND MEASURES.

The British Pharmacopæia employs both the Imperial and Metric denominations, giving the relative proportions side by side as in the N. F. It is to be hoped that the next edition of the U. S. P. will return to this arrangement as there does not seem to be any likelihood of the metric system being adopted as a uniform system for many, many years to come. So long as the avoirdupois system remains the standard of commerce it is idle to attempt to force upon pharmacists the adoption of another which is not "understood of the people."

GALENICALS.

This portion of the British Pharmacopæia has been very generally commended not only by the retail pharmacists but by those engaged in manufacturing on the large scale. The formulæ and processes are evidently the result of careful investigation and the preparations generally are worthy examples of pharmaceutical science. Especially is to be commended the omission of detailed description of operations which can only be satisfactorily performed on a large scale. In general the directions for preparation are concise and yet clear thereby saving much in the bulk of the book. One of the chief objections to the U. S. P. is the unnecessary amount of detailed description of processes for preparing galenical preparations. We might well take example from the British Pharmacopæia in this respect. How much simpler are the few words "Prepare by the maceration process," to the detailed and unnecessary instructions following the preparations of the U. S. P. The Pharmacopæia should presuppose a knowledge of the elements of pharmacy on the part of its users.

The most interesting addition to the last British Pharmacopæia was the class of "concentrated liquors" introduced to meet the demand for preparations which, when diluted, would represent the old infusions and decoctions. These liquors had for years been prepared by manufacturing houses and in spite of much adverse criticism the British Pharmacopæia formally recognized them. They are intended to represent a concentration of about ten times that of the simple infusion. They are prepared in some instances by maceration with water, expression and addition of alcohol to preserve, or by percolation with 20 per cent. alcohol, the process varying
A COMPARISON OF THE BRITISH AND U. S. PHARMACOPEIAS. 1163

according to the drug used. There are nine concentrated liquors in all
and they are used by diluting 1 part with 9 parts of water.

The following table shows the principal point of difference between the
galenicals common to the British Pharmacopeia and the U. S. P.

<table>
<thead>
<tr>
<th>Preparation</th>
<th>How Differs from the U. S. P.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acetum scillae</td>
<td>Stronger, 8 Cc. equals 10 Cc., U. S. P.</td>
</tr>
<tr>
<td>Alcohol</td>

SECTION ON PRACTICAL PHARMACY AND DISPENSING.

Name of Product.  How it Differs from U. S. P.
Calx sulphurata  "Not much less than" 50 per cent. of calcium sulphide.
Calx chlorinata  33 per cent. available chlorine.
Cinchona  5 to 6 per cent. total alkaloids.
Ferrum redactum  75 per cent. iron.
Opium  9.5 to 10.5 per cent. morphine.
Phenol liquefactum  90.9 per cent. phenol.

STANDARDIZATION.

It was a disappointment to English pharmacists to find so limited an application of standardization processes to galenical preparations, but the wisdom of the revisers' decision has since become apparent. It is far better to exercise care in selecting the best crude drugs for pharmaceutical preparations than to admit all kinds of crude material and depend for quality on processes of standardization that are such only in name in many instances. With the exception of cinchona and opium no crude drugs are required to conform to any alkaloidal standard. Belladonna, nux vomica, cinchona and ipecac preparations are all assayed and a higher standard is generally required than is the case with the U. S. P. products. None of the essential oils are quantitatively examined, the revisers relying altogether on physical constants as criteria of purity.

The assay processes for the galenicals follow well established lines but are somewhat different from those used in the U. S. P. In the case of ipecac the lead acetate process is employed and with nux vomica the strychnine is determined by the ferrocyanide process. With opium a check titration with decinormal sulphuric acid controls the gravimetric determination of the morphine content.

It is impossible in the limits of this paper to go into the details of the processes employed and it seems at this time unnecessary to deal with the B. P. at greater length as we are just on the eve of a new revision which promises to make a radical departure in British methods of pharmacopoeial revision.

LEGAL STATUS OF THE B. P.

The British Pharmacopoeia is not strictly speaking a legal standard and its position as a standard at all is not well defined. Neither the Medical Acts nor the Food and Drugs Acts refer to it in any way and the only British act which refers to it is the Pharmacy act of 1868 which stipulates that any person who shall compound any medicines of the British Pharmacopoeia except according to its formularies shall for each offence be liable to a penalty of five pounds. Such penalty must be sued for as provided in the act, that is by the Pharmaceutical Society. Proceedings, however, for compounding medicines according to other than the B. P. have never been instituted and so far this clause has remained a dead
letter. Nevertheless it is illegal to compound official preparations in any other way than according to the B. P.

In proceedings under the sale of Food and Drugs Act references are constantly being made to B. P. standards and it is interesting to note in this connection that under English law the custom of the trade or country is taken into consideration in the administration of certain acts. The B. P. has become consequently a custom of the country, and therefore, a person asking for any preparation official in the B. P. ought to receive a preparation made according to official formula. In the event that he does not receive such a product, the clause of the Food and Drugs Act which states that the law is violated if the article sold "is not of the nature, substance and quality demanded" would undoubtedly operate to convict the seller. Such has generally been accepted as the status of the B. P. under the Food and Drugs Act. This obviously applies only to compounded articles. There is no provision for regulating the sale of uncompounded articles although there have been numerous convictions under the act for the sale of such products which did not conform to B. P. standards. It is doubtful, however, if these convictions would be sustained in the event of an appeal to the higher courts. Even with compound products the position is by no means clear and there has been considerable demand for legislation which would accurately define the legal position of the B. P. and set at rest the much discussed question of standards under the Food and Drugs Act.

The Pharmacopoeia of Hungary was presented by A. R. L. Dohme, who said he would read only the general introduction and conclusion, on account of the length of the paper:

THE NEW HUNGARIAN PHARMACOPOEIA.

BY ALFRED R. L. DOHME AND HERMANN ENGELHARDT.

About twenty-five years after the issue of the Hungarian Pharmacopoeia, second edition, the new third edition has appeared. The latter must be considered a very valuable addition to the other pharmacopoeias which have appeared during the last decade, inasmuch as all the latest investigations as regards chemicals, preparations, etc., have been considered. In 355 pages the new pharmacopoeia deals with about 550 different chemicals and preparations, about 114 of which do not appear in the U. S. P. nor in the N. F. Besides the description of these chemicals and preparations, 98 reagents are described, while directions for only 7 volumetric solutions are given.

One paragraph deals with the utensils, apparatus and instruments which are to be kept in a drug store, while other chapters contain tables for the maximum doses, an enumeration of those poisonous substances which have to be kept under lock, a table for the number of drops in each gram of the various liquid chemicals and solutions, and tables for the physical constants of hydrochloric acid, sulphuric acid, nitric acid, phosphoric acid,
lactic acid, ammonia, potassium carbonate, etc. The following chemicals, which do not appear in the U. S. P., are given in the new Hungarian Pharmacopoeia:

Absinth  
Pyroligneous acid  
Acetosalicylic acid  
(Aspirin)  
Ethyl bromide  
Ethyl chloride  
Ether for narcosis  
Ethyl morphine HCl  
Marshmallow leaves  
Ammonium sulphoalcohololate  
Amylene hydrate  
Star anise  
Antidote for arsenic  
Antipyrin caffeine citrate  
Antipyrin salicylate  
Collemastrum of soap, salicylated  
Saffron  
Copper aluminate  
Zittmann's decoction  
Dextrin  
Electuaria  
Electuariun lenitivum  
Equisetum  
â-Eucaine HCl  
Euphorbium  
Extract belladonna with dextrin  
Extract henbane with dextrin  
Extract kola  
Leeches  
Mercury salicylate  
Hydromel infantum  
Laxative infusion  
Infusion of rhubarb  
Iris  
Solution of potassium acetate  
Potassium sulphoguaiacolate  
Potassium sulphide  
Leonuri lanata  
Surgical dressings (11)  
Storax liniment  
Liquor ammoniæ anisat.  
Liquor iron albuminate saccharated  
Peroxide of hydrogen 30 per cent.  
Malva flowers  
Malva leaves  
Manganese chloride  
Mannite  

Carbolized water  
Arecoline HBr.  
Protargol  
Bismuth tannate  
Bolus  
Castoreum  
Centaury  
Mustard plaster  
Quinine tannate  
Chloroform for narcosis  
Levant wormseed  
Codeine HCl  
Caffeine and sodium benzoate  
Caffeine and sodium salicylate  
Collemastrum of zinc oxide  
Chloroform oil  
Laurel oil  
Oil of pinus sylvestris for inhalation  
Sesame oil  
Root of oronides spinosa  
Poppy  
Lead carbonate  
Prune pulp  
Tamarind pulp  
Oak bark  
Pine resin purified  
Rob of juniper  
Rob of sambucus  
Salep  
Sambucus flowers  
Soaps (2)  
Squills dried  
Tallow salicylated  
Species  
Ethereal spirit of iron  
Antimony sulphide  
Syrup diacodi  
Syrup of potassium sulphoguaiacolate.  
Syrup of mannite  
Syrup of peppermint  
Tanninum albuminatum keratinatum  
Theobromine sodium salicylate  
Tincture of absinth  
Tinctura amara. (Bitter tincture)  
Tincture of castoreum  
Tincture of chamomile.  
Leaves of trifolium fibrinum
Honey of rose Cantharides ointment
Mixture of bromal hydrate Cerussa ointment

In the preface general rules for the use of the Pharmacopoeia by druggists, physicians and veterinarians are given and then the various methods for determining the physical constants of the chemicals and preparations are discussed.

A few of these methods may be mentioned here:—

The sp. gr. is to be taken at 15° C. by weighing 100 Cc. of the liquid or solution at this temperature. The weight should be taken to 1 decigram. The sp. gr. thus obtained should be checked by a hydrometer or Westphal balance, or in the case of alcoholic liquids, with an alcoholometer.

The melting point is determined in a manner similar to that given in the U. S. P. It is directed, however, that the substances should previously be dried at 100° C. and such substances which decompose, when being exposed to such a temperature, should be dried in a dessicator over calcium chloride or sulphuric acid at ordinary temperature.

The boiling point is also determined by a process similar to that of the U. S. P.

The congealing and melting points of fats and waxes are determined by transferring to a beaker of about 100 Cc. contents 50 Gm. of the melted and filtered mass. Then the contents of the beaker are stirred with a thermometer until a faint cloudiness appears. The temperature at which this occurs is considered as the congealing point. The contents of the beaker are then heated gradually until a clear mass is obtained. The temperature at which this takes place is considered as the melting point.

Acid and saponification number.—For the determination of the acid number, 5.6 Gm. of the fat to be examined are dissolved in 20 Cc. of neutral alcohol and after the addition of a few drops of alcoholic phenolphthalein solution, titrated with tenth-normal caustic alkali until a permanent pink color is produced. The number of Cc. of caustic alkali used is equivalent to the acid number. In the determination of the fats which are not liquid at ordinary temperatures a heating of the mixture of alcohol and fat is prescribed.

The determination of the bromine and iodine number of fats.—An accurately weighed amount of fat or oil varying in quantity according to the chemical composition of the fat is dissolved in 20 Cc. of carbon tetrachloride and to this 100 Cc. of tenth-normal bromine solution, 2 Gm. of potassium bromide, and 25 Cc. of diluted hydrochloric acid are added. The bottle is then closed well and placed in a dark place. After ½ hour
during which the bottle has been shaken frequently, 2 Gm. of potassium iodide are added, the mixture shaken again and then gradually tenth-normal thiosulphate solution is added until a colorless liquid is obtained. The Pharmacopoeia directs that starch solution as an indicator should be used only when the titration is carried out in artificial light, or when the end point of the reaction is difficult to be seen. From the figures found the bromine number as well as the iodine number can easily be calculated.

A special chapter is then devoted to sterilization. The containers which are used for keeping sterilized solutions should be heated either for two hours in a drying oven at 160° C. or should be boiled in water for 15 minutes. The sterilization of those substances which are not decomposed by boiling water is to be done by a current of steam or in the following way:—The containers to be filled with the sterilized solution are first wiped out with a pledget of cotton impregnated with alcohol, then with ether, and if a filtration of the liquid is necessary, the funnel is sterilized in the same way. The containers plugged with sterile stoppers are then heated for 1/4 of an hour at a temperature of 60 to 70° C. and this procedure has to be repeated if necessary, twice at intervals of one day each. Sterile ointments, oils and emulsions are prepared in a mortar previously cleaned with alcohol and ether.

Solutions.—The designation 1 to 10 or 1 to 20 means that one part of the substance is dissolved in nine or nineteen parts respectively of the solvents.

Size of drops.—For counting drops, a special dropper is prescribed, such as was adopted in 1902 by the Brussels Conference. 20 drops of distilled water should correspond to 1 Gm. at 15° C.

Temperature.—For measuring temperature, thermometers according to Celsius are to be used. 18° to 20° C is considered as the ordinary temperature. Digestions are to be made at 15° to 20° C., and macerations at 30° to 40° C. Specific gravities should be taken and reagents be made up at 15° C.

Preparations which are made according to the international formulas agreed upon in the Brussels Conference, 1902, are: Extract of belladonna leaves, extract of henbane, extract of nux vomica, extract of opium, extract of ergot, tincture of belladonna leaves, tincture of cantharides, tincture of colchicum, tincture of digitalis, tincture of ipecac, tincture of iodine, tincture of lobelia, tincture of nux vomica, tincture of opium, tincture of opium, camphorated, tincture of strophanthus.

It is directed that the following preparations be sterilized: electuary, extract of licorice, purified, solution of potassium acetate, surgical dressings and nutriments.

Preparations to be pasteurized are the following: infusion laxative, infusion of rhubarb, purified honey, prune pulp, tamarind pulp, rob of juniper, rob of sambucus, syrup of manna and syrup of senega.
The following drugs are to be renewed after keeping for one year: Belladonna leaves, digitalis leaves, henbane, mellea leaves, peppermint leaves, savin, prune pulp, rob of juniper, ergot, colchicum seed, linseed and tincture of colchicum.

The following preparations and drugs should be kept over calcium oxide (lime): mustard plaster, powdered extracts, dry squills and ergot.

The following preparations should be made by percolation: extract of belladonna leaves, fluidextract of cascara sagrada, fluidextract of cinchona, extract of cinchona, fluidextract of condurango, oleoresin of cubeb, oleoresin of malefern, fluidextract of golden seal, extract of henbane, extract of nux vomica, fluidextract of ergot, and tincture of orange for making syrup, tincture of belladonna leaves, tincture of cannabis indica and tincture of cantharides.

In the following most of those articles adopted by the Hungarian Pharmacopoeia may be mentioned, the requirements of which differ from those in the U. S. P., also those the adoption of which can be recommended for the next U. S. P.

**Acidum benzoicum.**—Only the acid prepared from benzoin is recognized, and the test for chlorinated products generally indicating the presence of artificial acid is carried out by mcstaining a mixture of .5 Gm. of pure calcium carbonate with .25 Gm. of the acid, drying and igniting the mixture. The residue is then taken up in pure nitric acid, which solution on addition of silver nitrate solution should not give a turbidity.

**Acidum carbo licum.**—An assay process for this chemical is not given.

**Acidum hydrochloricum concentratum.**—The Pharmacopoeia requires a sp. gr. 1.125, corresponding to about 25 per cent. of hydrochloric acid. This acid, therefore, is considerably weaker than that in the U.S. P., of which the sp. gr. is 1.158 at 25° C., corresponding to about 32 per cent. of hydrochloric acid.

**Acidum nitricum concentratum.**—The sp. gr. is given with 1.315 at 15° C., corresponding to 50 per cent. of absolute nitric acid, as compared with 1.403 at 25° C., corresponding to 68 per cent. of absolute nitric acid given in the U. S. P.

**Acidum phosphoricum.**—Only a diluted acid of 20 per cent. absolute phosphoric acid is official. It may be said here that the Hungarian Pharmacopoeia almost throughout uses Bettendorf's reagent for the detection of arsenic.

**Acidum sulphuricum concentratum.**—A 95 per-cent. acid is official, possessing a sp. gr. of 1.847 at 15° C. This acid is slightly stronger than that of the U. S. P., which requires only 92½ per cent. of absolute acid.

**Aconitum** is not official.

**Adeps lanae.**—In the test for cholesterols, the chloroform used for dissolving the woolfat, as directed in the U. S. P., is replaced by carbon-tetrachloride, which, as may be mentioned here, is very widely used in the tests given in the Hungarian Pharmacopoeia instead of chloroform or other
organic solvents. It is further directed that the wool fat should leave not more than 5 per cent. of ash on incineration. The acid number should be less than 1.

**Ether aceticus.**—The boiling point of this preparation is limited to from 74 to 76° C., therefore not having the wide range as given in the corrections of the U. S. P., i. e., 72 to 77° C.

**Ether depuratus.**—It is directed that if 10 Cc. of the ether be shaken with a saturated aqueous solution of calcium chloride the volume of the ether should not be decreased to any extent, thus allowing only very small quantities of water or alcohol.

**Ether pro narcosi.**—This preparation should have a sp. gr. not higher than .720 at 25° C. and should boil at exactly 35° C. The following test for the purity is given. 10 Cc. of ether shaken with 2 Cc. of water and a few drops of sulphuric acid should not produce a blue color on the addition of one drop of potassium dichromate solution. On adding to the ether a small piece of fused caustic potash and allowing the ether to stand in a dark place for six hours the potassium hydroxide should not be colored yellow. It is directed that the ether should be stored in amber bottles containing not more than 100 Cc. in a cold place.

**Aloes.**—When .05 Gm. of aloes are treated with 5 Cc. of nitric acid a red color should be produced. This shows that those species of aloes are official which are given in the U. S. P.

**Ammonium bromatum.**—The purity of this chemical is 98 per cent.

**Amylum nitrosum.**—It is required that this preparation should boil between 97° and 99° C. No assay process is given.

**Antifebrinum (acetanilide).**—The following test is given for the detection of acetanilide: When acetanilide is heated in a dry test tube with an equal amount of dry zinc chloride to 250° C. an odor of locust flowers is developed.

**Apopomorphine hydrochloride.**—A preparation of which a one per cent. aqueous solution turns green at once should be rejected. It is directed that the alkaloid be kept in dark bottles.

**Aqua amygdalarum amarum.**—The Pharmacopoeia directs that all the aromatic waters be prepared by distilling the volatile oils from the respective drugs by live steam. The distillate is allowed to stand for several days in well-closed bottles, with frequent shaking, and is then filtered through wetted paper. 100 Gm. of the filtrate should not be rendered turbid by hydrogen sulphide and should not leave a residue on evaporating to dryness.

**Aqua calcis.**—The Pharmacopoeia requires the lime water to contain not less than 0.13 per cent. and not more than 0.17 per cent. of calcium hydroxide.

**Aqua chlorata.**—The directions for making this preparation are: To 20 Gm. of coarsely powdered potassium dichromate, 200 Gm. of concentrated hydrochloric acid are added, the mixture is heated gently and the
chlorine gas absorbed by one liter of distilled water. The chlorine water thus obtained should contain .5 per cent. of chlorine gas.

_Aqua destillata._—Detailed directions are given for preparing distilled water from ordinary water, as regards the apparatus used for the distillation, the elimination of magnesium chloride, ammonia, organic matter, etc.; it is directed that only a sufficient quantity of water for immediate use be prepared.

_Balsamum copaiba._—The sp. gr. of the balsam is given as .94 to .99, thus allowing a balsam with only a comparatively small amount of volatile oil. No requirements for the acid and saponification numbers are given. As test for rosin the unreliable test with ammonia water is given.

_Balsamum Peru._—Fifty-six per cent. of cinnamenein is required. Acid and saponification numbers are not given.

_Balsamum tolu._—In the requirements for this drug the determination of the acid and saponification numbers are also omitted.

_Belladonnae folia._—No assay process is given. The only requirement is that the leaves should give by percolation with dilute alcohol 15 per cent. of extractive matter.

_Benzo._—The sp. gr. is given as 0.700 to 0.717. It is required that if 10 Cc. of the liquid be mixed with a cold mixture of 3 Cc. each of concentrated sulphuric acid and cold water the acid liquid should not turn yellow. Water shaken with benzin should not acquire an acid reaction.

_Benzoe._—Not more than 10 per cent. should be insoluble in warm alcohol.

_Bismuthum subgallicum._—This preparation should give on incineration 50 to 56 per cent. of bismuth oxide. The test for arsenic is made with Bettendorf's reagent.

_Bismuthum subnitricum._—Should leave on incineration 76 to 82 per cent. of bismuth oxide.

_Butyrum cacao._—The acid number should be less than 2, and the iodine number between 32 and 36.

_Calcaria chlorinata._—This preparation should contain 25 per cent. of available chlorine gas. The assay process is as follows: 3.55 Gm. are suspended in water and the volume made up with water to exactly 100 Cc. 10 Cc. of the suspension are transferred to a flask and mixed with 20 Cc. of water in which previously 1 Gm. of potassium iodide has been dissolved. The liquid is then made acid with 20 drops of hydrochloric acid and the separated iodine titrated with tenth-normal sodium thiosulphate solution, of which not more than 25 Cc. should be used.

_Calcium carbonatum precipitatum._—The test for nitrates with ferrous sulphate is given.

_Calcium hypophosphorosum._—This preparation should contain 90 per cent. of absolute calcium hypophosphite. This is determined by the following method: .21 Gm. of calcium hypophosphite is dissolved in sufficient
water to make 100 Cc. 10 Cc. of this solution mixed with 9 Cc. of tenth-normal potassium permanganate solution should decolorize the permanganate solution after the addition of 10 Cc. of diluted sulphuric acid.

_Camphora._—Only the natural product is official. The sp. gr. is given as .95, the melting point at 175° C. and the boiling point at 204° C.

_Cannabis Indica._—When extracted with alcohol it should yield 8 per cent. of extractive matter.

_Cantharides._—8 per cent. of ash is permitted.

_Capsicum._—Should yield not more than 5 per cent. of ash.

_Cera alba._—The acid number is given as 19 to 25 and the ester number as 68 to 75. The sp. gr. should be .966 to .970 and the melting point 64 to 65° C.

_Cera flava._—Sp. gr. 0.962 to 0.966, melting point 63° to 64°, acid number 19 to 23, ester number 68 to 75. A very circumstantial method is given for the determination of the specific gravity.

_Cetaceum._—The melting point is given as 47° C. The acid number should be not more than 1, and the iodine number between 6 and 7. 5 Gm. of cetaceum should be taken for the determination of the latter.

_Chinae succirubra cortex._—Only the red bark is official. The amount of total alkaloids should be at least 6 per cent. and the method for determining this is the same as recommended by Fromme and Keller, the alkaloids being titrated. The aqueous alcoholic liquid is then subjected to a qualitative test and for that purpose 20 Cc. are transferred to an evaporating dish, mixed with 10 Cc. of water, and evaporated on a water bath until 5 Cc. remain. 5 Cc. of water are added, and the mixture filtered through cotton into a cylinder and mixed with .5 Gm. of Rochelle salt. The mixture is then heated on a water bath for five minutes and allowed to cool. The crystals which separate are washed twice with 2 Cc. of water, then dissolved in 5 Cc. of water to which previously a few drops of diluted sulphuric acid have been added. To the fluorescent solution 2 Cc. of chloric water are added and 0.5 Cc. of ammonia water, when a green color should be produced.

_Chininum sulfuricum._—The Pharmacopoeia requires that the salt contain 8 molecules of water of crystallization.

For the detection of foreign cinchona alkaloids 1 Gm. of quinine sulphate previously dried at 100° C. is dissolved in a test-tube in 13 Cc. of hot distilled water and the test-tube then placed in a water-bath at exactly 15° Cc. and allowed to stand for two hours, maintaining exactly the same temperature. Then the liquid is filtered through a pledget of cotton and to the filtrate an equal volume of ammonia water is added, by which a clear solution should be obtained. This requirement is stricter than that given in the U. S. P. where for dissolving the precipitate of the alkaloids in 5 Cc. of the filtrate 7 Cc. of ammonia water are allowed. However, the requirements are not as strict as in the German Pharmacopoeia in which only 4 Cc. of ammonia water are permitted.
Another test is given. If 0.445 Gm. is dissolved in 10 Cc. of water with the addition of a little hydrochloric acid, this solution boiled with 10 Cc. of tenth-normal barium chloride solution, the mixture filtered, and the filtrate divided in two portions, the addition of barium chloride solution or the addition of diluted sulphuric acid to the filtrate should produce at most a turbidity.

**Chininum bisulfuricum.**—For determining the foreign cinchona alkaloids 1 Gm. is dissolved in a test-tube by heating with 20 Cc. of water. After cooling sufficient normal potash is added to the solution until a slight turbidity is produced. The test-tube is then put into water of 15° C., and the test carried out as given under quinine sulphate. A test with barium chloride solution and diluted sulphuric acid similar to that given under quinine sulphate, is given for this salt also.

**Chininum hydratum.**—For the detection of foreign cinchona alkaloids .5 Gm. is dissolved in a slight excess of sulphuric acid, after the addition of 20 Cc. of hot water. Then the mixture is heated and sufficient normal sodium hydroxide solution is added while still hot, until a faint cloudiness is produced. The process is then carried out as given under quinine sulphate.

**Chininum hydrochloricum.**—To detect the foreign alkaloids, 1 Gm. of the quinine hydrochloride is dissolved in 20 Cc. of warm water, and to this a solution of .5 Gm. of crystallized sodium sulphate in 5 Cc. of water is added. The test-tube is then placed in water at 15° C. and the process carried out as given before. Another test for the purity of quinine hydrochloride is the following: .397 Gm. is dissolved in 10 Cc. of water containing a few drops of nitric acid, and to this solution 10 Cc. of tenth-normal silver nitrate solution are added. The liquid is then filtered and the filtrate divided in two portions. To the one silver nitrate and to the other hydrochloric acid is added. In neither case should more than a turbidity be produced.

**Chininum ferri citricum.**—The method for making this salt is given in detail.

If 1 Gm. of the salt be wetted with nitric acid, the mixture heated and incinerated, about 0.3 Gm. of iron oxide should be left.

For determining the quinine, of which the salt should contain about 9 to 10 per cent., 3 Gm. are dissolved in an Erlenmeyer flask in 12 Gm. of water. To this solution 60 Gm. of ether and 6 Cc. of ammonia water are added and the mixture shaken at intervals for five minutes and then allowed to stand. Then 40 Cc. of the ethereal solution, equal to 2 Gm. of the salt, are filtered into an exactly weighed Erlenmeyer flask, the ether evaporated and the residue dried at 100° C. This residue should be not less than .18 to .20 Gm.

**Chininum tannicum insipidum.**—A detailed process for making this preparation is given, as well as a method for determining the amount of quinine present and the estimation of foreign cinchona alkaloids.
Chloroform pro narcosi.—The sp. gr. of this preparation is 1.485 to 1.489, the boiling point from 60° to 62° C. 10 Cc. of the preparation when allowed to evaporate spontaneously in a porcelain dish should not leave a residue nor a foreign odor. On shaking with an equal volume of water it should not impart to the latter an acid reaction, nor should the aqueous layer be rendered turbid by the addition of solution of silver nitrate. When shaken with an aqueous solution of potassium iodide (1 to 1000) the chloroform should not acquire a pinkish tint. When shaken with an equal amount of concentrated sulphuric acid the latter should not be colored within one hour. It should be kept in a dark room in dark bottles of not more than 100 Gm. capacity.

Codeinum hydrochloricum.—The test for cinchamylcocaïne is given as follows: 0.1 Gm. of the salt is dissolved in 5 Cc. of distilled water. To this 5 drops of concentrated sulphuric acid and two drops of tenth-normal potassium permanganate solution are added; the liquid should retain its pink color after standing for one hour.

0.340 Gm. of salt dissolved in 10 Cc. of distilled water are mixed with 10 Cc. of tenth-normal silver nitrate solution after the addition of some nitric acid. The mixture is then shaken well, heated and the filtrate divided into two parts. Neither the addition of hydrochloric acid nor the addition of silver nitrate should produce more than a faint turbidity.

Codeinum hydrochloricum.—Of the codeine salts only the hydrochloride is official. The following test for purity is given: 0.372 Gm. of the salt is dissolved in 10 Cc. of distilled water and to the solution, acidulated with a few drops of nitric acid, 10 Cc. of tenth-normal silver nitrate solution are added. The mixture is then shaken, heated and filtered, and the filtrate divided in two parts. Neither hydrochloric acid nor silver nitrate should produce a precipitate in the filtrate.

In a solution of 0.1 Gm. of salt and 5 Cc. of water 5 drops of normal sodium hydroxide solution should not produce a precipitate even after standing for one hour.

Colchici semina.—No assay process is given for this drug; it is only required that when extracted with alcohol 10 per cent. of extractive matter should be obtained.

Colloïdium.—5 Gm. are evaporated in a porcelain dish at a temperature not exceeding 25° C. The residue after drying over calcium chloride should weigh not less than 0.2 Gm.

Colocynthidis fructus.—Extracted with alcohol 30 per cent. of extractive matter should be obtained.

Colophonium.—When heated quickly the rosin should melt at 170° C. No determination of the acid number is given.

Decocta et infusa.—These are made by mixing the drug with the prescribed amount of cold distilled water and exposing this mixture to live steam in the case of infusion for five minutes. In the case of decoctions
for 30 minutes with frequent stirring. After cooling the liquors are filtered. Decoctions and infusions are supposed to be of 10 per cent. strength unless a stronger preparation is ordered by the physician. Both decoctions and infusions are to be made when prescribed and should never be kept in stock.

**Digitalis folia.**—The amount of extractive matter obtained by the extraction with alcohol should be 30 per cent.

**Emplastra.**—Plasters should be melted on a water-bath. Only resins which melt at a higher temperature are allowed to be melted over fire and are to be added to the balance of the plaster previously melted on a water-bath. Powders to be mixed with the plaster mass must be in a very fine state. The thickness of the plaster when spread should be 1 mm.

**Emplastrum diachylon.**—The following process is given for making this plaster: 500 Gm. of lead oxide are mixed in a roomy kettle with 500 Gm. of distilled water and to this 500 Gm. of lard and 500 Gm. of sesame oil are added. The mixture is then heated, replacing the water lost by evaporation, until the red color of the mixture turns to a yellowish white and until the mixture becomes sticky. The plaster is then washed with warm water and dried on a water-bath.

**Emplastrum hydrargyri.** This plaster is made with wool fat and diachylon ointment and should contain 20 per cent. of mercury.

**Emplastrum saponatum.**—This plaster also contains diachylon ointment as a base, and in addition to this white wax, camphor oil and 7 per cent. of dried medicinal soap.

**Emulsio amygdalina.**—This emulsion contains about 10 per cent. of sweet almonds and 5 per cent. of sugar. The acacia used in the U. S. P. is omitted.

**Extracta.**—The Hungarian pharmacopoeia distinguishes dry, thick, semi-liquid and liquid extracts, the dry extracts containing from 5 per cent. to 6 per cent., the thick extract from 15 per cent. to 25 per cent., the semi liquid from 25 per cent. to 40 per cent. and the liquid extracts from 65 per cent. to 85 per cent. of water.

For preparing the extracts only the best drugs should be used, and the maceration should be carried out at a temperature of 15° to 25° C.

For preparing the fluidextracts, first the weak percolate is evaporated at a temperature of 80° to 90° C. and the residue dissolved in the strong percolate. Ethereal percolates are to be evaporated at 35° C. on a water-bath. For preparing solid extracts the residue left after evaporation should be dried at a temperature not exceeding 50° C.

The percolation is carried out in an enameled or glass percolator, and in a manner similar to that prescribed in the U. S. P. taking 85 per cent. as reserve.

The determination of the moisture in the extract is carried out in the following way: 2 Gm. of the thick or semi-liquid extracts or 5 Gm. of the
liquid extracts are transferred to a glass dish with a flat bottom of 2½ cm. depth and 5 cm. diameter covered with a watch glass, and then dried at 100° C. to constant weight.

Detection of metals in extracts.—The extract is incinerated in a crucible and the ash dissolved in 5 Cc. of dilute hydrochloric acid. When the mixture is filtered the filtrate should not show a turbidity on the addition of a solution of potassium acetate and hydrogen sulphide water.

The extracts should be kept at ordinary temperature in a dry place in well-closed containers protected from light.

Extractum aloes.—It is directed that the identification of this extract should be carried out by the test given under aloes.

Extractum Belladonnae.—The extract is made by percolation with diluted alcohol in the regular way. Among various tests given for the identification of this extract the following may be mentioned, depending on the methylesculetine which is present in belladonna but not in the other mydriatic drugs. 0.5 Gm. of the extract is dissolved in water applying a gentle heat and shaken out with ether. The ethereal liquid when shaken in a test-tube with 10 Cc. of water and one drop of ammonia water should acquire a bluish-green fluorescence. The extract should contain not more than 10 per cent. of water. The following assay process is given: 4 Gm. of the extract are heated in an Erlenmeyer flask of 200 Cc. capacity with 4 Cc. of water. The mixture is allowed to cool and 80 Gm. of ether and 4 Cc. of ammonia water are added. The mixture is then shaken well for ten minutes and after standing for ½ hour, 60 Gm. of the ethereal solution are filtered into another Erlenmeyer, the ether evaporated and the residue treated twice with 5 Cc. of ether, which is evaporated each time. To the residue 30 Cc. of water saturated with ether are added and 10 Cc. of tenth-normal hydrochloric acid and the excess of acid titrated back in the usual way, using iodeosin as indicator. The amount of alkaloids is then calculated for dry extract as well as extract containing moisture, the latter being determined previously. No requirements for the amount of alkaloids present are made.

In addition to the quantitative determination a qualitative test depending on Vitali's reaction is given. An extract of belladonna containing dry dextrin is given also, which is made by dissolving the plain extract of belladonna in 100 parts of dilute alcohol, and adding to this such a quantity of dextrin, previously dried at 100° C., that on evaporation and drying an extract results which contains about 1 per cent. of total mydriatic alkaloids. The limit for the alkaloids present is from 0.91 to 1.06. This extract should be used for making pills, powders, solutions and suppositories and twice the quantity of extract prescribed should be used. In making plasters and ointments the strong regular extract of belladonna in the quantity prescribed should be used.

Extractum cannabis indicae.—This extract is made with alcohol, adding dextrin to the finished product.
Extractum cascarea sagradae fluidum.—This preparation should have a sp. gr. of 1.046 to 1.054 and should contain 25 per cent. of dry extract. The following identification test is given: 1 Gm. is dissolved in a small separator in 5 Cc. of water. To the solution 5 Cc. of ether are added and the mixture shaken occasionally during one hour. The ethereal solution is then transferred to a separator containing 1 Cc. of water and 1 Cc. of 10 per cent. ammonia water. On shaking, the ammoniacal liquid should assume a cherry-red color.

Extractum Chinæ fluidum.—This extract is made by macerating 500 Gm. of cinchona bark with 1500 Gm. of dilute alcohol, 40 Gm. of dilute hydrochloric acid and 50 Gm. of glycerin. The mixture is then transferred to a percolator and percolated with water in the usual way. The percolates are evaporated to 450 Cc. To the residue 50 Gm. of alcohol are added. By this process a clear transparent liquid is obtained with a sp. gr. of 1.130 to 1.160, which should contain 4 per cent. of total alkaloids, determined in the following way: Transfer 4 Gm. of the fluidextract to an Erlenmeyer flask of about 200 Cc. capacity, add to this 10 Cc. of water, 20 Gm. of chloroform, 60 Gm. of ether, and finally 5 Cc. of tenth-normal sodium hydroxide solution. The process is then carried out as given under cinchona. The thalleioquin reaction for identification is also prescribed.

Extractum Chinæ spissum.—This extract is made by percolating powdered cinchona bark with dilute alcohol. The extract should contain 12 per cent. of total alkaloids and is assayed in the following way: 1.25 Gm. are transferred to an Erlenmeyer flask of about 200 Cc. capacity and to this 50 Gm. of ether, 25 Gm. of chloroform, 5 Cc. of fifth-normal caustic potash and 10 Cc. of water are added. The mixture is shaken well for fifteen minutes and then allowed to stand for one-half hour. The ethereal liquid is then filtered through cotton and 60 Cc. transferred to another Erlenmeyer. The ether is evaporated and the residue treated once more with 5 Cc. of ether. The dry residue is then dissolved in 30 Cc. of alcohol, litmus solution added and then gradually tenth-normal hydrochloric acid until a red color is produced. 3.9 Cc. of hydrochloric acid should be used. With the liquid after neutralization the thalleioquin reaction is made.

Beside the last-mentioned reaction other identification tests are given for both the fluid and solid extract of cinchona.

Extractum cubebe.—The oleoresin is made by extracting the powdered cubebs with a mixture of equal parts of ether and alcohol.

Extractum filicis.—The pharmacopoeia directs that the malefern be extracted with ether, which in our opinion is much better than acetone, inasmuch as the latter is liable to extract substances which might produce injurious after effects.

If .25 Gm. of the oleoresin is dissolved in 2 Cc. of ether and the solu-
tion shaken with 10 Cc. of lime water and the liquid filtered through a wetted filter, hydrochloric acid will produce an abundant white precipitate in the filtrate. The extract when viewed under a microscope should not show any starch.

**Extractum gentianae.**—It is directed to macerate 1000 Gm. of the finely powdered gentian with 5000 Gm. of water, to strain and to macerate the marc again with 3000 Gm. of water. After standing for 12 hours the mixture is filtered again, and the marc pressed out well. The combined liquids are then evaporated on a water-bath until a weight of 2000 Gm. is obtained and this residue is mixed with 1000 Gm. of alcohol added in small portions. The alcoholic liquid is then filtered through and evaporated until 100 Gm. of the soft extract contains 75 to 80 Gm. of dry extract.

**Extractum hydragis fluidum.**—It is directed to macerate the powdered golden seal with 500 Gm. of dilute alcohol and to exhaust the drug by percolation with dilute alcohol. The weak percolates are evaporated to 150 Gm. and the residue treated with 50 Gm. of alcohol. To this solution the reserve is added, the mixture stirred well and filtered.

An extract with the sp. gr. of .970 to .985 is thus obtained of which 100 Gm. contain 20 Gm. of dry extract. The extract should contain not less than 2 per cent. hydrastine which is determined by the following method: 12 Gm. of the extract are weighed into an Erlenmeyer flask of about 100 Cc. capacity and 20 Cc. of water are added. The mixture is then heated until the liquid is evaporated to about 1/2 of its volume. To the residue 2 Cc. of diluted hydrochloric acid and sufficient water are added to make the total weight of the liquid 20 Gm. After the addition of 0.5 Gm. of talcum powder and thorough shaking the mixture is filtered through a small filter. 10 Gm. of the filtrate corresponding to 6 Gm. of the extract are transferred to another Erlenmeyer of about 150 Cc. capacity. 30 Gm. of ether and 5 Cc. of ammonia water are added and after shaking well for five minutes 30 Gm. of petroleum ether are added and the mixture shaken well again. The ethereal liquid is then filtered and 50 Gm. of the filtrate are evaporated until 10 to 11 Gm. are obtained. The remaining liquid is set in a cool place and after two hours the supernatant liquid is decanted from the crystals which have separated. The crystals are washed with 2 to 3 Gm. of petroleum ether and dried at 100° C. to a constant weight. This residue should amount to 1 Gm.

.02 Gm. of the residue are then dissolved in 10 Cc. of water containing a few drops of dilute sulphuric acid, and to this 2 drops of tenth-normal potassium permanganate solution are added and the mixture shaken until colorless liquid is obtained. After a few minutes the liquid will show a blue fluorescence.

**Extractum hyoscyami** (*formula internationalis*).—The extract should not contain more than 10 per cent. of water. No assay process is given
for this extract, but the following reaction is used for identification: Dissolve .75 Gm. of the extract in 5 Cc. of water in a bottle, add 15 Cc. of ether and .3 Gm. of calcium carbonate. (Should probably read sodium carbonate. E.) Shake well for five minutes, then add 3 Gm. of dry sodium sulphate and shake again for ten minutes. Allow to clear and decant 5 Cc. of the clear ethereal liquid into a porcelain dish. Add to this 3 Cc. of water and evaporate off the ether on a water bath. The aqueous liquid is filtered through a pledget of cotton into another dish, evaporated to dryness and to the residue Vitali's reaction is applied. To the balance of the ethereal solution not used for this test add one drop of dilute sulphuric acid and 3 Cc. of water. Then evaporate off the ether, filter the aqueous liquid through a pledget of cotton into another test-tube and add to this solution Wagner's reagent, which should produce a reddish-brown precipitate. In addition to this extract the pharmacopoeia has an extract diluted with dextrin.

**Extractum kolae fluidum.**—As this extract is not official in the U. S. P., it is not necessary to give a process for making it as outlined in the Hungarian Pharmacopoeia. The extract, which is required to contain 1 per cent. of caffeine, is assayed by the following method: Exactly 12 Gm. of the extract are weighed into an Erlenmeyer flask of about 100 Cc. capacity and heated until two-thirds of its volume are lost. The liquid is then allowed to cool and 10 Cc. of water in small portions, 60 Gm. of chloroform and 3 Cc. of ammonia water are added. The mixture is shaken well for one-half hour and allowed to stand for one-half hour. 50 Gm. of the chloroform liquid are taken off with a pipette and transferred to another Erlenmeyer. To this chloroform extract 20 Cc. of ½ per cent. hydrochloric acid are added and the chloroform evaporated. The aqueous liquid is then filtered into a separator and shaken with 20, 15, 10 and 5 Cc. of chloroform. The combined chloroformic solutions are filtered and collected in a weighed Erlenmeyer, the chloroform distilled off and the residue dried to a constant weight. 0.1 Gm. should be obtained and identified as caffeine with chlorine water and ammonia. (It is difficult to understand why the acid liquid is not made alkaline with ammonia. By not doing so the basic theobromine is not determined. E.)

**Extractum liquoritiae.**—100 Gm. of powdered licorice are macerated for one day with 4000 Gm. of distilled water, filtered, the marc pressed out well and macerated again with 2000 Gm. of distilled water for two hours. The mixture is then filtered, the marc pressed out again and the combined aqueous liquids evaporated on a water-bath until 2000 Gm. of liquid are obtained. The liquid is allowed to cool and 1000 Gm. of alcohol are added, the mixture shaken well, filtered and the liquid evaporated on a water-bath until 100 parts of the soft extract contain 60 to 65 parts of dry extract.

**Extractum malatis ferri.** This preparation which is official in the N.
Extractum nucis vomicae.—(Formula internationalis.) This extract which is made with dilute alcohol should contain when dry 16 per cent. of total alkaloids. It is assayed in the following way: Weigh into an Erlenmeyer of about 200 Cc. capacity 1.25 Gm. of the extract and dissolve it with gentle heating in 10 Cc. of water. To the cold liquid add 50 Gm. of ether, 25 Gm. of chloroform and 3 Cc. of ammonia water. Then shake well for 1/4 hour, and allow to stand and clear. Of the ethereal liquid filter 60 Gm. (equal to 1 Gm. of extract) into an Erlenmeyer of about 200 Cc. capacity, evaporate off the menstruum used and titrate in the usual way, with tenth-normal acid and tenth-normal sodium hydroxide.

With the ethereal liquid which is not used for the estimation identification reactions for strychnine and brucine are made.

Extractum opii.—(Formula internationalis.) For the preparation only water is used. The assay process for this extract is the well-known Helfenberg process.

Extractum rhei.—The following identification process is given: .05 Gm. of the extract is dissolved in a small separatory funnel in 5 Cc. of water and the solution then tested in the way given under extract cascara sagrada.

Extractum ratanhiae.—This extract is made with water only. For the identification of this extract .25 Gm. are dissolved in hot water, the solution cooled and 5 Cc. of alcohol are added, whereby a clear solution will result. Two Cc. of this solution are diluted with 20 Cc. of water and divided into two parts. To the one portion one drop of iron chloride solution is added, whereupon a yellow flocculent precipitate will separate. To the other one drop of ammonia is added, by which a reddish color will be produced.
Extractum scille.—This extract is not made with acetic acid as directed in the U. S. P.

Extractum secalis cornuti spissum.—This extract is made in the following way: 1000 Gm. of ergot are macerated for twelve hours with 2000 Gm. of chloroform water. The mixture is strained and the marc pressed out well. The latter is then macerated again for six hours with 2000 Gm. more of chloroform water and the mixture strained again, etc. The combined aqueous solutions are evaporated on a water bath to 500 Gm. and to this 400 Gm. of alcohol are added. The mixture is shaken well occasionally during one hour, filtered through filter paper and evaporated on a water bath until 165 Gm. of the residue are obtained. By this way an extract results of which 1 Gm. is perfectly soluble in 5 Cc. of water. This mixture should not be rendered turbid by the addition of 5 Cc. of alcohol. The aqueous solution has an acid reaction. 5 Gm. of the extract is dissolved in 5 Cc. of water in a small separatory funnel, and to this solution 10 Cc. of ether and sufficient ammonia water is added to produce an alkaline reaction. This mixture is then shaken and, after clearing, the ethereal liquid is filtered into a porcelain dish and the ether evaporated off on a water bath. The residue is dissolved in 3 Cc. of glacial acetic acid, transferred to a test-tube, one drop of normal iron chloride solution is added and the liquid underlaid with concentrated sulphuric acid, when at the zone of contact a blue ring should appear. One part of the extract represents six parts of ergot.

Besides this extract the pharmacopia recognizes an extract which is mixed with dextrin in such a quantity that two parts of the extract contain one part of dry extract.

Extractum secalis cornuti fluidum.—The fluidextract of ergot is prepared by mixing 500 Gm. of powdered ergot with 25 Gm. of glycerin and 275 Gm. of alcoholic cinnamon water. The mixture is then transferred to a percolator and the ergot exhausted with a mixture of 20 parts of alcohol (by weight) and 80 parts of water. The percolation is carried out in the usual way, keeping 425 Gm. as reserve, evaporating the weaker percolates on a water-bath to 75 Gm. and dissolving the residue in the reserve. After settling, the fluidextract is filtered through filter paper. By this way a preparation is obtained with a slight acid reaction and a sp. gr. of 1.07 to 1.08.

3 Gm. of the extract are mixed in a porcelain bowl with 7 Gm. of water and the mixture evaporated until 5 Gm. of the residue are obtained. The cold liquid is then transferred to a separator and the test for cornutine made as given under extract ergot.

Ferrum hydrogenio reductum.—Dissolved in hydrochloric acid it should not leave more than 1 per cent. of insoluble matter. A test for the absence of cyanides is given and it is also required that the gas produced by the action of the sulphuric acid on the iron should not produce any
change when conducted into silver nitrate solution in the latter within 5 minutes. The reduced iron should be 80 per cent. pure but no proper assay is given. If 1 Gm. of the iron is heated for fifteen minutes the resulting oxide should weigh 1.34 Gm.

**Ferrum lacticum.**—The following process is given for determining the percentage: If 1 Cm. of the iron lactate be moistened with concentrated sulphuric acid in a porcelain crucible, and the mixture dried and ignited, about .27 Gm. of iron oxide should be obtained.

**Ferrum pulveratum.**—Should contain not more than 1 per cent. of matter insoluble in hydrochloric acid.

**Ferrum sesquichloratum crystallisatum.**—The following test is given for ferrous salt: If 1 Gm. of the iron chloride be dissolved in 100 Cc. of water and this solution be acidulated with 20 Cc. of hydrochloric acid not more than 5 Cc. of tenth-normal permanganate solution should be used to produce a persistent red color. No assay process is given.

**Ferrum sesquichloratum solutum.**—This solution should have a sp. gr. of 1.28 to 1.283 and should contain about 10 per cent. of iron.

**Filicis Maris rhizoma.**—Should yield 8 per cent. of extractive matter when exhausted with ether.

**Formaldehyde solutum.** (Formalin.)—This preparation should have a sp. gr. of 1.077 to 1.081 and should contain about 35 per cent. of absolute formaldehyde. A mixture of 2 Cc. of formaldehyde solution and 1 Cc. of tenth-normal sodium hydroxide solution should not show an acid reaction. For the determination of the percentage the iodometric method is used, which is carried out as follows: 1.5 Gm. of the formaldehyde solution are diluted with water to measure 100 Cc. and of this solution 5 Cc. are mixed with 50 Cc. of tenth-normal acid potassium iodate solution, 2 Gm. of potassium iodide and 5 Cc. of hydrochloric acid. The liquids are mixed well, and, after the addition of about 5 Cc. of caustic soda, allowed to stand for 10 minutes. The mixture is then acidulated with 10 Cc. of hydrochloric acid and the separated iodine titrated with tenth-normal thiosulphate solution. For retitration 32 to 33 Cc. of the latter solution should be used.

**Guarana.**—Guarana should contain 4 per cent. of caffeine. The assay process is as follows: 6 Gm. of guarana, previously dried at 100° C., are mixed in an Erlenmeyer flask with 120 Gm. of chloroform and 6 Cc. of ammonia water, and after shaking well for some hours, the chloroformic liquid is filtered. 100 Gm. of the filtrate are then evaporated and to the residue 3 Cc. of alcohol are added. The solution is evaporated again, the residue dissolved in a mixture of alcohol and water (3 to 7) and after adding 20 Cc. of water the solution is filtered into a tared beaker and evaporated to dryness. The white crystalline residue should weigh 0.2 Gm.

**Gummi Arabicum.**—Should yield not more than 5 per cent. of ash.
**Hydrargyrum bichloratum corrosium.**—The following test is given for this chemical: 1.36 Gm. of corrosive sublimate are dissolved in 50 Cc. of warm water and saturated hydrogen sulphide water is added. The resulting precipitate is then filtered and washed with 50 Cc. of water. The filtrate is boiled and after cooling, 2 to 3 drops of methyl orange solution are added. 9.9 to 10.1 Cc. of normal potassium hydroxide should be used for neutralizing this liquid. The precipitate produced by the hydrogen sulphide water is tested for arsenic in the regular way.

**Hydrastis Canadensis radix.**—No assay process is given.

**Hyoscyami folia.**—No assay process is given, the only requirement being that the leaf should yield on extracting with alcohol 18 per cent. of extractive matter.

**Ipecacuanhae radix.**—It is required that the root should contain 2 per cent. of total alkaloids, which are determined in the following way: 5 Gm. of the powdered ipecac are mixed in an Erlenmeyer flask with 75 Gm. of ether, and shaken occasionally during \( \frac{3}{4} \) hour. Then 4 Cc. of ammonia water are added, the mixture shaken again for \( \frac{3}{4} \) hour and allowed to stand for \( \frac{3}{4} \) hour, after which 60 Gm. of the ethereal liquid are filtered into an Erlenmeyer flask and the ether evaporated. The residue is twice treated with 5 Cc. of ether which is evaporated each time. Then 30 Cc. of water saturated with ether are added and 10 Cc. of tenth-normal hydrochloric acid. After solution has taken place 90 Cc. of water are added and a few drops of iodeosin and the excess of acid titrated back in the usual way.

**Jalape radix.**—The jalap should contain 8 per cent. of resin, which is to be determined by extracting the root with alcohol and purifying the resulting resin by treating it with hot and cold water.

**Iodium.**—Should be 99 per cent. pure and free from iron.

**Kalium bromatum.**—The following test is given for purity: 1.19 Gm. are dissolved in sufficient water to make 100 Cc. To 20 Cc. of this solution a few drops of nitric acid and 20 Cc. of tenth-normal silver nitrate solution are added and the mixture filtered. The filtrate should not produce more than a turbidity, either by the addition of hydrochloric acid or by the addition of silver nitrate solution.

**Kalium carbonicum purum.**—The following test is given to determine the purity of this salt: The salt is heated to a red heat, and after cooling in a dessicator, 1.38 Gm. are dissolved in 10 Cc. of distilled water. After the addition of one or two drops of methyl orange the solution is neutralized with normal hydrochloric acid, of which 19.8 Cc. should be used.

**Kalium chloricum.**—The test for nitrates is made with zinc and iron and not with aluminum, as directed in the U. S. P.

**Kalium hydrocarbonicum.**—5 Gm. heated in a crucible should leave 3.44 to 3.45 Gm. of residue.
Kalium hydroxidatum.—Should contain 80 per cent. of absolute potassium hydroxide.

Kalium hypermanganicum.—The purity is determined by the iodometric method and should be 99.5 per cent.

Kalium hypophosphorosum.—Should contain 90 per cent. of absolute potassium hypophosphite, which is determined in the following way: .26 Gm. of the salts are dissolved in sufficient water to produce 100 Cc. of solution and 10 Cc. of the solution are mixed with 9 Cc. of tenth-normal potassium permanganate and then with 10 Cc. of sulphuric acid. The potassium permanganate should be decolorized.

Kalium jodatum.—The following purity test is given: If 1.66 Gm. are dissolved in sufficient water to make 100 Cc. and 20 Cc. of this solution be mixed with 20 Cc. of tenth-normal silver nitrate solution, after adding a few drops of nitric acid and filtering it should yield a filtrate in which no turbidity is produced either by the addition of hydrochloric acid or by the addition of silver nitrate solution.

Kalium stibio tartaricum.—The following purity test is given: 3.32 Gm. are dissolved in sufficient water to make 100 Cc. of solution. To 10 Cc. of this solution, 20 Cc. of hydrochloric acid, a few drops of methyl orange and 10 Cc. of tenth-normal bromine solution are added at once and then drop by drop sufficient of the same solution until the reddish-blue color changes to lemon yellow. 19.8 to 20 Cc. should be used.

Kole Semina.—No assay process is given.

Kreosotum.—The sp. gr. is given as 1.08 to 1.09 and the boiling point from 200° to 220° C. It should not become solid even when cooled to —20° C.

Linimentum saponato camphoratum.—The following process is given for making this liniment: 50 Gm. of powdered soap are dissolved with the aid of heat in 70 Gm. of water, and to this 820 Gm. of alcohol are added and the mixture heated on a water-bath with frequent stirring until the soap is perfectly dissolved. Then 25 Gm. each of camphor and ammonia water, 5 Gm. each of oil of lavender and oil of rosemary are added, and sufficient alcohol to make the total weigh 100 Gm. The mixture is then filtered.

Liquor ferri albuminati.—120 Gm. of iron oxychloride solution are mixed with 3380 Gm. of water previously heated to 50° C., and to this is added a filtered solution of 240 Gm. of fresh egg albumen in 3250 Gm. of water, also heated to 40° C. The precipitate thus produced is allowed to settle and the supernatant liquid decanted. After washing with 3500 Gm. of water of 40° C. the precipitate is transferred to a strainer and allowed to strain until 500 Gm. of iron albuminate are obtained. This is then dissolved in 20 Cc. of normal sodium hydroxide solution and to the resulting solution 100 Gm. of alcoholic cinnamon water, 2 Gm. of aromatic tincture, 50 Gm. of alcohol and sufficient water are added to produce
a total weight of 1000 Gm. By this process a red, limpid liquid is obtained, free from the taste of iron and miscible with alcohol. It should contain 0.4 per cent. of metallic iron, which is determined iodometrically as given under Extractum malatis ferri.

Liquor ferri oxychlorati.—This preparation, for which a detailed process for making it is given, should contain 3½ per cent. of metallic iron, which is determined iodometrically by a method similar to that given under iron salts.

Liquor hydrogenii hyperoxidati concentratissimus.—Only a preparation containing 30 per cent. of absolute peroxide of hydrogen is recognized. This mixture should not give a reaction with sulphuric acid nor with calcium chloride, after being made alkaline with ammonia. It is to be kept in bottles which are covered inside with paraffin. The quantitative determination is the same as that given in U. S. P. with potassium permanganate solution. In a foot note it is directed that when ordinary peroxide of hydrogen is prescribed, a 3 per cent. solution should be made from the stronger solution.

Lithium carbonicum.—The purity for this chemical is 99 per cent.

Lobelia herba.—When extracted with diluted alcohol it should yield about 18 per cent. of extractive matter.

Magnesium oxidatum.—10 Gm. heated to redness in a crucible should lose not more than 1 Gm.

Mel.—A mixture of one part of honey and 20 parts of water should have a sp. gr. of 1.111. 10 Gm. of the honey dissolved in 20 Cc. of water should not require more than 4 Cc. of normal sodium hydroxide solution for neutralization, phenolphthalein being used as indicator.

Morphine and its salts.—Only morphine hydrochloride is official.

Natrium boricum.—1.91 Gm. of borax dissolved in water should require 9.9 to 10.1 Cc. of normal acid for neutralization.

Natrium bromatum.—The test for purity is similar to that given under Kalium bromatum.

Natrium carbonicum cryst.—The purity should be at least 99 per cent.

Natrium hydroxydatum.—Should contain 90 per cent. of absolute sodium hydroxide. The test for purity is carried out in the following way: 4.01 Gm. are dissolved in sufficient water to make 100 Cc. To 20 Cc. of this solution 15 Cc. of barium chloride solution are added, and a few drops of phenolphthalein solution, and then sufficient normal hydrochloric acid to discharge the red color. 18 Cc. of acid should be used.

Natrium hypophosphorosum.—This salt should contain 90 per cent. of hypophosphite. The determination is carried out in a manner similar to that given under potassium hypophosphite.

Natrium salicylicum.—1 Gm. of the salt on incineration should yield .33 to .34 Gm. of residue.

Nitroglycerinum spiritui solutum.—The quantitative determination of this
solution is carried out by adding to 7.57 Gm. of the nitroglycerin solution 20 Cc. of tenth-normal hydroxide solution free from carbonates. After the addition of phenolphthalein, the excess of the alkali is titrated back with tenth-normal acid, of which 9.05 (should probably read 9.5 Cc. E.) to 10.5 Cc. should be used representing about 1 per cent. of nitroglycerin in the solution.

*Nucis v a semina.*—Should contain 1½ per cent. of total alkaloids, which are determined in the following way: To 5 Gm. of the powdered drug 25 Gm. of chloroform and 50 Gm. of ether are added, and after allowing to macerate for one-half hour 4 Cc of ammonia water are added. The mixture is shaken well during one quarter of an hour. After allowing to stand for one hour the ether-chloroform mixture is filtered and 60 Cc., equal to 4 Gm. of the drug, are transferred to another Erlenmeyer of 200 Cc. capacity. The process is then carried out as given under ipecac.

*Oleum amygdalarum dulcium.*—The acid number for this oil should be less than 3, and the iodine number 94 to 96. 0.7 Gm. are taken for determining the latter.

*Oleum camphoratum.*—For this oil and for
*Oleum chloroformatum* sesame oil is used.

*Oleum cinnamomi cassiae.*—The oil as distilled from the leaves of Cinnamum Cassiae is official. The sp. gr. is given at 1.055 to 1.065.

*Oleum fecoris aselli.*—The sp. gr. is given as .920 to .930. The acid number should be less than 2, and the iodine number, for the determination of which 4 Gm. are taken, should be between 150 and 155.

*Oleum lini.*—The acid number should be less than 2, the iodine number, for the determination of which 0.3 Gm. are taken, should be between 170 and 180.

*Oleum phosphoratum.*—This preparation is made in the following manner: 94.5 Gm. of oil of sweet almonds are mixed with 10 Gm. of dry sodium sulphate and heated on a water bath for one-half hour with frequent stirring. Then the mixture is allowed to cool to a temperature below the melting point of phosphorus and 0.5 Gm. of dry phosphorus is added and mixed well until the odor of phosphorus has disappeared. To this solution 5 Gm. of alcohol are added, by which a limpid and transparent yellowish oil is obtained. 2 Gm. of phosphorized oil should contain .01 Gm. of phosphorus.

*Oleum pini sylvestris pro inhalatione.*—It is interesting to note that this oil, which is used considerably for inhaling purposes, is official in the pharmacopoeia. The sp. gr. is given as .853 to .870. It should be perfectly soluble in ether and twice its volume of alcohol.

*Oleum sinapis aetherium.*—No assay process is given.

*Opium.*—Opium dried at 60° C. should contain 10 per cent. of morphine. This is determined in the following way: The opium is first freed from the poppy leaves and the seeds of the various species of rumex
with which the gum opium is usually covered and dried at 60° C. 6 Gm. of the dried powdered opium are then transferred to a porcelain dish and stirred with 10 Cc. of distilled water to a uniform mixture. This mixture is then transferred to a tared Erlenmeyer with sufficient water to make the solution weigh 54 Gm., and this mixture is shaken well for one-fourth hour. 42 Cc. of the aqueous liquid are filtered through a filter of 8 Cm. diameter into a cylinder, mixed by gentle rotation with 2 Cc. of normal ammonia water and the process then finished as given in the Helfenberg method. Opium which contains more than 10 per cent. should be mixed with sufficient milk sugar to reduce the strength to 10 per cent. of morphine.

Pastilli (tablets).—Tablets should not weigh more than 1 Gm. They should be prepared by compressing the powder or granulated material; they should be easily friable between the fingers, and should also be easily soluble in warm water. As lubricants, talcum powder, cacao powder or paraffin are allowed.

Only two kinds of tablets are described, nitroglycerin tablets, of which each tablet should contain .0005 Gm. of nitroglycerin, and santonin tablets, of which each tablet should contain .125 Gm. of santonin. Both the tablets are prepared with milk sugar and powdered cacao.

Pepsinum.—The proteolytic power is determined in the following way: A hen's egg is cooked for five minutes and the coagulated albumin integrated through a No. 4 sieve. (No. 25 U. S. P.) 10 Gm. of the disintegrated albumin are transferred to a cylinder and mixed with 95 Cc. of water at 50° C. and 2 Cc. of hydrochloric acid. The mixture is then shaken well and .1 Gm. of pepsin, dissolved in 3 Cc. of luke-warm water, is added. The mixture is then kept in a water bath at 40° C. and shaken every ten minutes; the albumin, with the exception of a few particles of membrane, should be dissolved within one hour. This would correspond to a pepsin 1.600, which requirement is considerably less than that of the U. S. P.

Pilulae.—Pills for internal use should have a weight of from .1 to .3 Gm. and when cut in half and shaken with luke-warm water should disintegrate or dissolve within a short time. For making pills the following details are given:

The pill mass should be perfectly uniform and kneadable.

As binders and diluents various substances are given, the former including extract licorice, water, alcohol, glycerin, simple syrup, acacia, and the latter comprising powdered licorice root, powdered marshmallow root, sugar and milk sugar.

Pills which contain silver nitrate, mercury preparations or similar substances which act on organic matter are to be made with bolus and glycerin.

Pills containing balsams should be made by mixing the mass with wax.
The pills should be rolled in powdered licorice root.

*Pilulae ferri carbonici*—The following formula is given for Blaud’s pills: 30 Gm. of pure potassium carbonate are mixed in a mortar with 30 Gm. of powdered sugar, then with 60 Gm. of finely powdered crystallized ferrous sulphate, and to the mixture 4 to 5 Gm. of pure honey are added, and mixed well again. Of this mass 500 pills should be made each of which contains .05 Gm. of ferrous carbonate.

*Plumbum aceticum basicum solution.*—No assay process is given. Sp. gr. should be 1.23 to 1.24.

*Pilulae laxantes.*—These are made from powdered aloes, powdered jalap root and powdered medicinal soap, and are flavored with oil of anise.

*Podophylli resina.*—One part of resin should be soluble in 100 parts of ammonia water, and water added to this solution should not produce a turbidity.

*Potio magnesiae citricae effervescens.*—8 Gm. of magnesium carbonate are mixed with 300 Gm. of distilled water and to the mixture 14.5 Gm. of crystallized citric acid are added. After the effervescence has ceased 40 Gm. of simple syrup, 1 drop of lemon oil and 3 Gm. of sodium bicarbonate are added and the mixture filled in strong bottles. This mixture contains 12 Gm. of magnesium citrate and 3 Gm. of sodium citrate.

*Powders.*—Only the best materials should be used.

Grind the material to a coarse powder and dry at a temperature not exceeding 60° C. If the ingredients contain volatile substances the temperature should not exceed 30° C. The duration of the heating depends on the nature of the material and the amount of it. Musk, castoreum, crocus, digitalis leaves, ergot and malefern are to be dried and kept over calcium oxide and should be powdered only when used.

The materials should be powdered if possible without leaving a residue. The finished powders are dried again and kept in well-closed containers. The vegetable powders are to be renewed every year and the powders containing aromatic substances should be made only when used.

*Pulvis liquiritiae compostus.* The powder contains 1 Gm. of oil of anise, 40 Gm. of powdered sugar, 10 Gm. of washed sulphur, 20 Gm. of powdered licorice, and 20 Gm. of powdered senna leaves.

*Punice granati cortex.*—The following test is given for determining the proper amount of alkaloids present in the drug. Add to 4 Gm. of the finely powdered drug 20 Cc. of ether, shake for a few minutes and then add 2 Cc. of water and 2 Cc. of fifth-normal sodium hydroxide solution. Mix thoroughly by shaking for one minute and allow to stand for one-quarter hour, then filter the ethereal liquid into a porcelain dish containing about 5 Cc. of water acidulated with hydrochloric acid. Evaporate off the ether, filter the acid liquid and add to the filtrate 1 to 2 drops of Wagner’s reagent, by which a reddish precipitate should be produced.
Rhataniae radix.—By extraction with hot water 9 per cent. of extractive matter should be obtained. The alcoholic extract mixed with a solution of lead acetate should give a red-colored precipitate. The filtrate from this should possess a red color also.

Resina elastica.—The following test for the purity of caoutchouc is given: 0.5 Gm. of the rubber cut in small pieces is dissolved in 25 Cc. of petroleum ether with frequent shaking and the mixture allowed to stand for 12 hours. The mixture is then filtered into a tared Erlenmeyer and the insoluble matter washed twice with 5 Cc. of petroleum ether. To the solution in the Erlenmeyer 40 to 50 Cc. of absolute alcohol are added. The alcoholic liquid is then decanted from the precipitate and the latter washed with 5 Cc. of absolute alcohol. Flask and precipitate are then dried on a water bath to a constant weight. 0.42 to 0.43 Gm. of pure rubber should be obtained.

Resina jalape.—Should contain no more than 10 per cent. of ether-soluble resin. 0.2 Gm. of resin jalap dissolved in 2 Cc. of acetic acid should not be colored red or green by the addition of 1 Cc. of concentrated sulphuric acid.

Resorcinum.—The melting point is given 100° to 111° C.

Saccharinum.—The following test for purity is given. Dissolve 0.366 Gm. in 20 Cc. of hot distilled water and after the addition of a few drops of phenolphthalein in solution add sufficient tenth-normal sodium hydroxide solution free from carbonates, until a pink color is produced. 19.6 to 20 Cc. of the latter should be used.

Saccharum lactis.—The test for cane sugar is the same at that in the U. S. P., i.e. treating the milk sugar with dilute alcohol.

Sal carolinum factitium.—This salt contains 220 Gm. of sodium sulphate, 10 Gm. of potassium sulphate, 90 Gm. of sodium chloride, and 180 Gm. of sodium bicarbonate.

Sapo Kalinus and Sapo medicinalis are made with sesame oil.

Scopolaminum hydrobromicum.—This salt should melt at about 190° C. An aqueous solution should not be rendered turbid by the addition of ammonia water.

Secale cornutum.—Ergot should yield 16 per cent. of extractive matter when exhausted with alcohol.

Spiritus camphoratus.—The following test is given: 10 Cc. of the spirit of camphor are shaken in a test-tube with 10 Cc. of a solution of calcium chloride and 4 Cc. of petroleum ether: the volume of the latter should be increased to 5 Cc. The sp. gr. is given as .896 to .898.

Spiritus concentratissimus.—Should contain 94.1 to 96 per cent of absolute alcohol by volume. Among the tests the following is given: If 10 Cc. of alcohol are mixed with 0.5 Cc. of tenth-normal potassium permanganate solution the red color should not be discharged within 10 minutes.

Spiritus dilutus.—Should contain 69.8 to 70.2 per cent. of absolute alcohol by volume.
Strophanthi semina.—When extracted with alcohol strophanthus should yield 12 per cent. of extractive matter. Only the Kombó seeds are official.

Strychnium.—Of the strychnine salts, only strychnine nitrate is official.

Suppositoria.—Should be made with oil of theobroma or when other fatty oils, glyco-gelatin or stearin-soap. They may be formed by hand or made in moulds. Ordinary suppositories should be 3 to 4 cm. long and should have a diameter at the wider part of 1 cm. The thickness of urethral suppositories should be 2 to 3 Mm.

Syrups.—Syrups should be prepared by gently heating the sugar with the prescribed amount of the other ingredients. Concentrated syrup is prepared by heating sugar and water for a short time, until a clear solution is obtained, replacing any water lost by evaporation.

Syrups containing vegetable extracts or fruit juice should be pasteurized.

Syrupus ferri jodati.—To 25 Gm. of powdered iron suspended in 50 Cc. of cold water 8.2 Gm. of iodine are gradually added. When the color of the latter has disappeared, the solution is filtered into a porcelain dish containing 125 Gm. of sugar and 0.2 Gm. of citric acid and the filter is washed with sufficient water to obtain 200 Gm. of total filtrate. The mixture is then heated to dissolve the sugar and any water lost by evaporation is replaced. The following test for this syrup is given: 15.5 Gm. of the syrup are dissolved in sufficient water to make 100 Cc. of solution. To 20 Cc. of this 10 Cc. of tenth-normal silver nitrate solution and a few drops of nitric acid are added, and the mixture filtered. In the filtrate either silver nitrate or hydrochloric acid should produce no more than a faint turbidity.

Syrupus hypophosphitum comp.—Contains 15 Gm. of calcium hypophosphite, 10 Gm. each of potassium hypophosphite and sodium hypophosphite, 5 Gm. each of iron lactate and citric acid, 2 Gm. each of manganese chloride and quinine hydrochloride, 550 Gm. of sugar and 15 Gm. of tincture of nux vomica and q. s. water in 1000 Gm.

Tinctures.—Tinctures are to be prepared by maceration and percolation generally in the proportions of 1 part of the drug to 10 parts of the menstruum, as adopted by the Brussels conference, 1902. Stronger tinctures (20 per cent.) of indifferent drugs are allowed also.

Tincture aloe.—Should contain 9 per cent. of extractive matter.

Tincture belladonna. (Formula internationalis.)—Should contain 2½ per cent. of extractive matter. The following test is given: 10 Cc. are evaporated and the residue mixed with 10 Cc. of cold water. The mixture is then filtered and the filtrate is divided into two parts. With one part of the filtrate Vitali's reaction is made in the usual way, while in the other the presence of methylesculetine is proven.

Tinctura Chinae.—Should contain 5½ per cent. of extractive matter. No assay process is given.
Tinctura colchici. (Formula internationalis.)—Should contain 3 per cent. of extractive matter. The following test is given: Evaporate 10 Cc. of the tincture to dryness, take up the residue in 5 Cc. of chloroform and 10 drops of ammonia water, and shake well for two minutes. Filter the chloroformic liquid into a porcelain dish, evaporate to dryness, take up the residue in 5 drops of concentrated sulphuric acid and add a few crystals of potassium nitrate. A bluish-green color changing to violet-red should be produced.

Tinctura digitalis. (Formula internationalis.)—Should contain 3½ per cent. of extractive matter. The following test is given: 10 Cc. are evaporated to dryness and the residue taken up in 10 Cc. of distilled water, mixed well with 5 drops of basic lead acetate solution and the mixture filtered. To the filtrate 10 Cc. of chloroform are added and the mixture shaken well for two minutes. The clear chloroformic liquid is then evaporated on a water bath to dryness, the residue dissolved in 3 Cc. of glacial acetic acid, to which one drop of one-half-normal iron chloride solution has been added and the mixture then underlaid with 2 Cc. of concentrated sulphuric acid. A blue ring should be produced at the zone of contact.

Tinctura ipecacuanhae (Formula internationalis.)—Should contain 2 per cent. of total alkaloids, which are determined in the following way: 32 Gm. of the tincture ipecac are evaporated in an Erlenmeyer until 10 Gm. are obtained. To the cold residue 60 Gm. of ether and 2½ Cc. of ammonia water are added and the mixture shaken well for one-fourth hour. After allowing to stand for one-half hour, 45 Cc., equal to 2 Gm. of the tincture, are filtered and evaporated in an Erlenmeyer. The process is then carried out in the usual way.

Tinctura malatis ferri.—Should contain .5 per cent. of iron, which is determined iodometrically.

Tinctura nucis vomicae.—Should contain .25 per cent. of total alkaloids, which are determined by a process similar to that given under nux vomica.

Tinctura opii.—Should contain 1 per cent. of morphine, which is determined by evaporating 50 Gm. of the tincture in a porcelain bowl until 15 Gm. are obtained. To the residue sufficient water is added to produce 38 Gm. Then 2 Gm. of normal ammonia water are added, the mixture rotated and 32 Gm., equal to 40 Gm. of the tincture, are transferred to an Erlenmeyer, and the morphine determined by the Helfenberg process.

Tinctura opii crocata.—Should contain 1 per cent. of morphine, and is assayed in a way similar to that for the tincture opium.

Tincture strophanthi.—Should contain 2 per cent. of extractive matter and should answer the following test: If one drop of the tincture be evaporated in a porcelain dish and to the dry residue 4 drops of 8 per cent.
sulphuric acid and two drops of water are added, a green color will be produced.

*Tinctura veratri.*—Should contain 1.6 per cent of extractive matter and answer the following test: 10 Gm. of the tincture are evaporated on a water-bath with the addition of three drops of dilute hydrochloric acid until 3 Gm. are obtained. To this residue 7 Cc. of water are added, the mixture filtered into a separatory funnel, 5 Cc. of ammonia water and 5 Cc. of ether are added, and the mixture shaken well. After the ethereal solution has become clear, it is filtered into a porcelain bowl and evaporated to dryness. To the residue fuming hydrochloric acid is added, by which on heating a red color should be produced.

*Unguenta.*—Precautions similar to those given under *Plasters* should be observed.

Ointments in which granules or liquids have separated or in which the ingredients are not properly mixed, so that they can be seen with the naked eye, and rancid preparations, should be rejected.

The ointments should be kept in a cool place in proper containers, preferably those made of porcelain.

*Unguamentum acidi boricci.*—This ointment is prepared with paraffin, sesame oil, and glycerin.

*Unguamentum diachylon Dr. Hebrae.*—Lard is heated with lead oxide and water and to this petrolatum and oil of lavender are added.

*Unguamentum hydrargyri.*—The constituents of this ointment are 300 Gm. of mercury, 100 Gm. of hydrous wool fat, 50 Gm. white wax and 550 Gm. of lard, giving an ointment with 30 per cent. of mercury. The latter is determined by a method similar to that of the U. S. P.

*Unguamentum zinci oxydati.*—The ingredients for this ointment are: White wax 25 parts, liquid petrolatum 225 parts, anhydrous wool fat 225 parts, zinc oxide 25 parts.

*Vina medicamentosa.*—Only tokay wine is official, which should contain 15 per cent. of alcohol.

From the foregoing it may be seen that the new Hungarian Pharmacopoeia must be considered as a perfectly up-to-date work.

In four points this pharmacopoeia does not agree with most of the other pharmacopoeias published during the last decade.

1. The exclusive use of Bettendorf's reagent for the detection of arsenic in chemicals, etc.

2. The extensive use of seame oil in place of olive oil and other fats in making ointments, oleates, etc.

3. The restricting the use of wine, to the single brand, the domestic tokay wine.

4. The lack of assay processes for volatile oils.

*Baltimore, April, 1910.*
Mr. Wilbert said there were several points about the Hungarian Pharmacopoeia that were worth bringing out. To begin with, it was printed in two languages, the first part in Latin and the other in Magyar. He thought the Latin Edition was the official. A description was added, rather than an appendix. He said they seemed to be at a loss there for an editor, and had evidently discovered that the Latin portion of the book did not conform to the Magyar. Austria-Hungary, while one country, was an empire composed of two absolutely different peoples, with different ideals and different languages; and if there was anything that the Hungarians hate, it was an Austrian or anything Austrian.

The Chair remarked that the Croats had still another Pharmacopoeia. The Chair asked Mr. Dohme what he thought about the value of sesame oil, which had been put in most all of the Pharmacopoeias, but had been dropped from the U. S. Pharmacopoeia.

Mr. Dohme replied that he thought it was well adapted for keeping preparations; that it kept better than the other oils, as it contained a small per cent. of acid. Why the committee had dropped it, he did not know, unless it was not a commercial article. He said that when he was in France he found that sesame oil was very much used by pharmacists; that they preferred it to any fatty oil they could get.

The Chair said he much preferred it to olive oil.

A paper upon the Japanese Pharmacopoeia, by J. Takamine, was read by title and referred, in the absence of the author:

REVIEW OF THE JAPANESE PHARMACOPEIA, THIRD EDITION, OFFICIAL SINCE JANUARY, 1907.
BY DR. J. TAKAMINE, N. Y. CITY.
HISTORICAL SKETCH, FIRST EDITION.

In 1880, the Director of the Board of Hygiene submitted the first project for founding a national Pharmacopoeia to the Minister of Home Affairs; the latter transmitted the project with recommendation to the Cabinet. It was approved and forthwith the government commissioned the Central Council of Health, a chartered organization composed of both medical and pharmaceutical professions, to undertake this pioneer task of compilation of Pharmacopoeia. A committee was appointed and the members thereof set to work according to the various branches of tasks they were assigned to. Informal meetings were followed by general conferences, and after five years investigations and studies the first draft was completed to be submitted to the Minister of Home Affairs.

In 1886 it was published and became official next year. It contained 470 articles in the text and the appendices included several important tables, list of reagents, and volumetric solutions, and general rules regarding pharmaceutical preparations. A Latin translation was also published.
In view of limited knowledge of medicine and pharmaceutical chemistry at the time of compilation, this pioneer task has been carried through commendably and laid the foundation for the Revision Committee appointed later. Several German and Dutch gentlemen of the medical and chemical profession, then in the employ of the government, shared a great credit in this undertaking whose participation has not since been required, as the country has made phenomenal progress in every branch of science.

SECOND EDITION.

No sooner had the first edition become official than it was generally felt necessary to revise the pharmacopoeia in order to keep up with the rapid progress in the field of medicine and pharmacy, as the country has been unceasingly progressing to cope with it. A Revision Committee of ten was duly appointed from among the medical and pharmaceutical professions of the country and consisted of ten members.

After numerous investigations and due discussion, the Revision Committee completed a draft for the second edition which became official in 1892. A Latin translation was published at the same time. In this edition 23 articles found admission and 67 met the fate of expurgation. More than 1500 changes were introduced.

THIRD EDITION.

In 1900 the statute with respect to the revision of the pharmacopoeia was enacted and established a permanent commission for that work. The statute provides that the Revision Committee shall be under the supervision of the Minister of Home Affairs; that it shall consist of a president, sixteen members of committee and two secretaries. The president, committee and chief secretary are appointed by the Cabinet in accordance with the recommendation of the Minister of Home Affairs. The members of committee and chief secretary are to receive each a sum not exceeding yen 500 (or $250) and the under secretary yen 100 (or $50) annually.

With the enactment of the statute, committee and other officials were duly appointed. The committee consisted of eleven chemists and five physicians. More thorough studies and investigations were made than for the previous revision. 119 informal conferences, 70 general meetings and 30 special conferences for members in charge of compilation have brought to fruit the publication of the present edition. Nearly six years elapsed before the draft was submitted to the Minister of Home Affairs for recommendation.

Changes in the text amounted to more than 815, and more or less alterations in each of the texts were made. In fact, it was practically rewritten. 224 articles were admitted and 23 omitted. The text, therefore, now contains 695 articles.
Most medicinal substances more or less in general use were admitted in this edition. Disinfecting materials and disinfectants were adopted. In the arrangement of text, Latin names of articles were chosen to be set in alphabetical order. Chemical substances, whose constitution is fully established, were represented with their empirical formula, which followed Latin names. Atomic and molecular weight and Japanese names of articles were printed next in order. Oxygen was taken as standard. Size of test tubes and quantity of sample solutions to be taken were unified; selecting test tubes of nearly $1\frac{1}{2}$ centimeter diameter into which 10 Cc. of the solution shall be taken. Method of preparation is specifically given only when there is the necessity of unifying the quality of the preparation.

For measure and weight the metric system is used while temperature is measured with Centigrade, $15^\circ$ of which is fixed as normal. Melting point is directed to be determined under uniform condition as specified. Fineness of powder is fixed and the temperature of maceration and digestion is put at $15^\circ$ to $25^\circ$ C. for the former, $35^\circ$ to $45^\circ$ C. for the latter. Drying of drugs shall never exceed $40^\circ$ C.

In glancing over the text, those articles of known chemical constitution present no special aspect, since their quality and adulterations, etc., can be determined by ordinary chemical means. Among them, however, it is noticeable that 17 new remedial substances of known chemical constitution and therapeutic value are adopted, notwithstanding they are of more or less proprietary nature, such as aspirin, trional, urotropin, etc. These are however, admitted with chemical nomenclature, discarding those of registered mark. As to galenical preparations, general rules are given with the provision that special descriptions are to be found for each in the text where these rules are not applicable. A brief abstract of these subjects will follow.

EMPLASTRUM—PLASTER.

Unless specially prescribed, melt high-fusing ingredient first, then mix thereto the low-fusing substance. When molten mass partially cools, add medicaments and thoroughly mix and make into a suitable form as it cools down and assumes a homogeneous appearance.

Plaster is a solid mass at ordinary temperature but becomes plastic when warmed to body temperature. It should melt by warming further. Keep in a cool place packed in sheath or opaque paper. If the medicament is volatile, keep the same in closely covered tin.

EXTRACTS.

An extract is duly extracted from the drug for use as specified and evaporated on water bath with continual stirring at a temperature not exceeding $85^\circ$ C. for aqueous and alcoholic extract and $35^\circ$ C. for ethereal extract.
Extracts are divided into 3 classes:
No. 1 "Thin" extract: consistency of honey.
No. 2 "Thick" extract: stringy but not decantable.
No. 3 "Dry" extract: dry and reducible to powder.
Narcotic "Dry" extract is prepared by mixing 4 parts of No. 2 with 3 parts of licorice powder, and drying on water bath and making up to 8 parts after trituration and addition of sufficient quantity of licorice.
Instead of above, a narcotic extract may also be kept in a liquid state, which is accomplished by dissolving 10 parts of No. 2 extract in 6 parts of water and adding thereto 1 part alcohol and 3 parts of glycerin.
When 2 grammes of an extract is incinerated and the ash dissolved in 5 Cc. of dilute hydrochloric acid and filtered, the filtrate shall present no change by addition of hydrogen sulphide water.
Where proportion of ingredients is given, it signifies proportion by weight throughout whole text.

**EXTRACTA FLUIDA.**

In preparing fluidextract quantity of yield shall always be in same quantity as the material taken. Specially mentioned menstruum found in the text is sprinkled uniformly over 100 parts of the material until it no more absorbs the fluid. Whole is set aside for 2 or 3 hours under tight-fitting cover. Then the mass is packed uniformly into a suitable percolator, in which maceration is continued for 24 hours at the temperature of from 15° to 20° C. After the lapse of time, the liquid extract is drawn off at the rate of 40 drops per minute. 85 parts are thus taken and set aside. The remainder is extracted with as much fresh menstruum as necessary to exhaust material, and after combining the dilute fluid thus obtained is evaporated to a thin extract and dissolved in 85 parts of percolate first set aside. Leave same for a day or two at rest and filter after making to 100 parts with an sufficient quantity of fresh menstruum.
Test for the presence of metal is conducted as same as under Extracta, taking 2 grammes of sample.

**INFUSION.**

Boiled water is poured over the drugs finely cut and heated for 5 minutes on a water-bath, with frequent shaking. Strain after cooling.
If no specified prescription is given by the physician, it is taken for granted that 10 parts of infusion are to be made from 1 part of drugs.
Quantity of potent drugs must always be strictly described on the prescription.

**PASTILS.**

In default of any special prescription, pastils are made of finely powdered medicament with milk sugar as vehicle. Mixture is moistened with dilute alcohol and moulded to suitable shape weighing each 1 Gm. If shape cannot be made a little addition of gum arabic is allowed.
PILLS.

The ingredients shall first be thoroughly mixed and usually licorice powder or extract is used for shaping. They shall be made of uniform size weighing one-tenth gramme each, except in case where special prescription directs otherwise. Lycopodium or licorice is generally used for coating.

ROOTS.

Two roots are of Japanese origin and may be of interest to describe.

Radix gentianae scabrae.
(Gentiana scabrae Bge var. Burgeri Max.)
Radix hibisci.
(Hibiscus japonica, Mig.)
The former is the substitute for Gentian and the latter for Althæa.

SPECIES—TEAS.

Cut, rasp or crush drugs and remove fine powder and obtain as uniform size as possible; mix them together. According to the facility with which infusion of the ingredients of drugs, different grade of division must be given to the materials. Tea-mixture is of a fine cut and that for fomentation is of coarse powder.

SERA.

Antidiphtheric and antitetanic sera are adopted, each in liquid and solid form.

Antidiphtheric serum in liquid form is required to possess a power of not less than 500 units in 1 Cc. as determined in accordance with Behring and Ehrlich method. It shall not be used if turbid or if it shows any precipitate, and must not be kept over one year. Three classes are mentioned.

No. 1, 600 antitoxic units.
No. 2, 1000 antitoxic units.
No. 3, 1500 antitoxic units.

Solid serum shall be of 5000 units. Antidiphtheric as well as antitetanic sera shall be kept sealed in a glass vessel with the label bearing the name of factory, the strength expressed in units of antitoxic power possessed by 1 Cc., the quantity of contents, the number of application and finally the date when it was tested.

SUPPOSITORIES.

Except in special cases cacao butter is employed as vehicle. Medicament is to be mixed alone with vehicle or some suitable liquid may be added if the conditions call for it. Potent and poisonous medicines are not allowed to be put up in hollow suppositories unless prescribers request it.

Shape of suppositories is cylindrical, spherical, conical and oval according to the convenience for use.
A rectal suppository is usually of a length of from 3 to 4 Cm. and 1 to 1½ Cm. in diameter at the base of cone, weighing from 2 to 3 Gm. A vaginal suppository should weigh from 4 to 6 Gm.

**Syrups.**

Unless special mention is made in the text they are prepared by dissolving required medicines in simple syrup or dissolving with sugar in the required proportion. Heating is once brought to boiling point of water and strained through cloth while still hot.

Keep in a bottle well filled. Those which show signs of fermentation or those which deposit precipitates shall be discarded.

**TeLa—Gauze.**

Antiseptic cotton or gauze such as boric, carbolic and salicylic acid, mercury bichloride, iodoform, first found admission in this edition.

**Tincturae.**

Unless specially described drugs of medium cut and coarse powder are macerated in the menstruum and the vessel is kept closely covered in a cool place, shaken frequently during 7 days' maceration.

Strain and leave for several days to allow the deposit to settle and then filter with cover of glass plate over the funnel. Tinctures shall be kept in a cool, shady place.

**Unguenta—Ointments.**

In order to prepare ointment, melt the base which liquifies with ease unless otherwise instructed, then add thereto that which melts with difficulty. Mix finally medicament into molten mass, when partially cooled, until a homogeneous mass is obtained. Those which decompose quickly must be prepared fresh for use. When a rancid odor is developed it shall be discarded.

**Vina—Wines.**

The preparations and preservation of wines should be conducted according to same mode and precaution as described under "Tincturae."

Principal points in the text have so far been covered and what still remains to be added are the appendices. They are as follows:

No. 1. Reagents.
No. 2. Volumetric Solutions.
No. 3. Articles found in the text, which shall always be kept in any dispensary.
No. 4. Articles of the text which belong to the poisonous class and are required to be kept in the place under lock and key.
No. 5. Articles of the text which are classed as potent and requested to be kept separate from ordinary ones.
No. 6. Doses for adults, with special instruction that physicians should not be allowed to prescribe over-doses unless they mark their special purpose with exclamation point (!) on their prescription.

No. 7. Atomic weight of elements that are met with in the text. Oxygen taken as standard.

No. 8. Comparative list of chemical names with those of proprietaries.

The Japanese Pharmacopoeia is the statute and its publication was made in the official gazette at the time of enactment. No individual can have the sole privilege of copy-right. It can be printed by any printer, so that nobody can monopolize the sale of the book.

Whilst a Latin translation of official nature was published for the first and second edition no translation for the present edition was made. However, it was desirable to have a translation and the Pharmaceutical Society of Japan has undertaken the task in persuance of the desire shown both from official and private side. The English language was selected for the simple reason that it is the language which is most popularly used in Japan for foreign intercourse. The translation is a solid cloth-bound book of 424 pages.

The Chair said the Japanese Pharmacopoeia leaned upon the U. S. P. The original, he said, was printed in Japanese, but he had before him a translation in English. This translation, however, contained a number of errors, some of which he pointed out.

Mr. Wilbert said the Japanese Pharmacopoeia had also been translated into German, and that the pharmacopoeia itself was really based on the German. The original was written in German, and translated into Japanese. A number of Germans had gone to Japan, and they took quite a prominent part in the making of the pharmacopoeia.

The Chair said they had also taken a great many ideas from the American Pharmacopoeia, as medicinal waters, etc.

The Mexican Pharmacopoeia was reviewed verbally by Mr. C. A. Mayo, who also exhibited a copy of the book itself, and explained its features:

The Chair remarked that the Mexican Pharmacopoeia was the first pharmacopoeia published after the Brussels International Conference.

Mr. Wilbert explained the method of the Mexican Pharmacopoeia in giving a general formula, and then enumerating some 25 or 30 others that might be made by that formula. He said the same was true of tinctures and alcoholic extracts. All through the book that feature was observed. It was printed in Spanish with English and Latin titles.

The subject of the Netherlands Pharmacopoeia was presented in the following paper by Henry Kraemer.

76
THE NETHERLANDS PHARMACOPEIA.

BY HENRY KRAEMER.

On recommendation of the Secretary of the Interior, her Majesty, the Queen, decreed on March 8, 1899, that a commission consisting of ten members be appointed to revise the Netherlands Pharmacopœia (Pharmacopœa Nederlandica).

The Commission as first appointed was constituted as follows: Five university professors, two of whom were professors in pharmacy, one a professor in botany, one a professor in chemistry, and one a professor in pharmacology; four practical pharmacists, and a chairman, who was the chief of the Board of Health.

The personnel of the original Commission was, however, somewhat changed through the death of two members and the resignation of two others, one of whom subsequently died.

Thus, the committee finally responsible for the work of revising the fourth edition of the Netherlands Pharmacopœia consisted of the following members:

1. Dr. H. Wefers Bettink, director of the Pharmaceutical Institute and professor of pharmacognosy, toxicology and chemistry, University of Utrecht, chairman.
2. H. P. Wijsman, professor in pharmacy, University of Leiden.
5. Dr. H. Zeelhuisen, Army surgeon.
6. P. A. Vos, pharmacist in Rotterdam.
7. J. Guldensteeden Engeling, apothecary in the Province of Zeist.
9. L. van Itallie, pharmacist of Rotterdam, now professor in the veterinary school in Utrecht.
10. Dr. M. Greshoff, director of the Colonial Museum in Harlem.

Before beginning the work of revision proper, the Commission asked the national society of medicine and the national society of pharmacy to make such recommendations as they deemed advisable, and they were given until January 15, 1900, in which to consider the matter and formulate their recommendations and suggestions. The Commission also took measures to obtain the views of physicians and pharmacists in the Dutch Colonies of the East and West Indies in regard to the manner in which the Pharmacopœia could be improved so as to suit their needs.

After considering the question in all of its bearings they determined to make a pharmacopœia which could be used both in the Netherlands and in the Colonies, giving such alternate formulæ as were necessary to meet the conditions, in the colonies, one of these being the tropical climate. Thus, in the case of ointments requiring 20 to 30 per cent. of adeps or
vaseline, provision is made for replacing these bases with cera flava or paraffin. In the case of the Indian drugs the local synonyms are appended at the end of the paragraph describing the drug, as for example, in the case of Curcuma, where the synonym, temoe lawak, is given.

The Commission, after having completed the work of revision, embodied the proposed corrections, additions and other changes in a supplement, which was published in 1902. Two or three years were then allowed to elapse in order that the proposed changes might be thought over and their merits and applicability in practice determined. After this preliminary testing of the new Fourth Edition it was published in 1905 and became the official standard on July 1, 1906.

The new work was first printed in Hollandese (Dutch) and then translated into Latin. The Latin edition contains about 550 pages, and is printed in clear type. The book happily combines the results of careful experimental work and improved methods required in the practice of modern pharmacy, and may be said to be the most complete and scientific of any of the national pharmacopoeias.

While it is manifestly impossible to consider in extenso the various interesting features of the New Netherlands Pharmacopoeia in the brief time at my disposal, I shall point out some of the general principles which maintained in the revision of the work, and perhaps call attention to some of the individual drugs and classes of preparations.

One of the notable features of the Netherlands Pharmacopoeia, and which makes it a model for an international pharmacopoeia, which it is in a certain sense, is that due to the adhesion of the Commission to the standards adopted by the Brussels Conference for the Unification of the Formulæ of Potent Medicaments. While the agreement for adopting these standards was not signed until November 29, 1906, that is, five months after the Pharmacopoeia became official, the standards were practically adopted as proposed by the Brussels Conference in 1902, and the initials “F. I.” (Formula Internationalis) are given after the title of each preparation of the potent drugs, as “Tinctura Aconiti, F. I.”

The descriptions of the official articles are uniformly complete, rather than what might be termed adequate, as is the case in most of the other pharmacopoeias. In practice this is found to be of very great importance, as one is not able to say that a supposedly insignificant character is not of importance at times. If uniform standards mean anything, especially with such potent drugs as aconite and digitalis, for which settled standards have not been provided, it would seem reasonable that the descriptions of the vegetable drugs, as they are the most indefinite substances on the market, should not only be accurate but fairly complete, so as to preclude the chance for misinterpretation. In the Netherlands Pharmacopoeia these descriptions are frequently as complete as those for the alkaloids and other chemical substances, and in some instances much longer.
The titles for articles and the nomenclature are similar to those in the Third Edition. The main titles of the articles correspond in general to those customarily used in European pharmacopoeias, with the exception of the chemical salts, where the acid radical precedes the name of the base, as Iodetum Kalicium for potassium iodide, and Benzoas natricus for sodium benzoate. While this is contrary to general custom, it may have some advantages, as the physician will find the iodides, benzoates and so on grouped together in their respective classes. The titles of vegetable drugs for the most part include a prefix which indicates the part of the plant used, as Cortex Granati, which title corresponds to the Granatum of the U. S. Pharmacopoeia. Under the principal title a synonym is frequently given, as for example, Aqua Calcis, the synonym for Solutio Hydratis Calcici. Common-name synonyms as we know them in this country, are not given, except in the case of the East Indian drugs, already mentioned. This also would seem to have an advantage in that greater uniformity in prescription-writing would obtain.

Vegetable Drugs.—In the definitions of vegetable drugs it is noticeable that the names of families to which the plants belong are replaced by a citation of the literature giving the original description of the plant, as under Radix ipecacuanhæ, where we read, "Radices adventicæ tumefactæ quas præbet Psychotria ipecacuanhæ, Stokes, Bot. Mat. Med. I, 365 (Uragoga ipecacuanhã, Baill. Hist. Pl. VII, 281).

The macroscopic descriptions are complete, and written in such a manner as to indicate that it is expected that dried drugs, such as leaves, will be softened before examination, and frequently the characters described are those requiring the use of a hand lens magnifying five diameters. The histological characters are also carefully described, including descriptions of both longitudinal and transverse sections of a number of drugs.

The powdered drugs are fully described, frequently at considerable length, beginning with the more important and prominent characters and extending to the less characteristic features. The descriptions are based on examinations made with the following reagents: Water, chloral hydrate solution, and chloral-iodine solution, and in special cases other reagents may be employed. It is furthermore directed that if the pharmacist has any question as to the authenticity of the sample examined he shall compare it with the powder of a drug, the identity of which is known or has been established.

It should be emphasized that this is a very important rule to observe. Considerable stress is laid upon the size of the tissues and cell contents and the manner of stating the measurements is quite a novel one.

As every one knows there are certain discrepancies in the literature with regard to the length of the fibers, size of starch grains, number of carpels, etc. In order to prepare accurate statements based on statistics which would allow for uncertain variations the latter were arranged in
such a manner that the curve of probability would indicate the different possible errors. This is determined as follows: The number indicating the minimum size is subtracted from that of the maximum size and the half of the remainder, known as the quarter (Quartilis) is taken to represent the probable mathematical error. The average (or median) size is obtained either by subtracting the quarter from the maximum or adding it to the minimum. The average size or the average number is indicated by \( M \) and the probable variation above or below this is indicated by \( Q \), and thus we find under the description of the fibers of powdered cinnamon that \( M \) is equivalent to 480.5 microns and \( Q \) equals 55.7 \( \mu \), and thus one would expect to find a variation ranging from 433.8 to 545.2 \( \mu \).

In those cases where the curve of probability of error would be in asymmetry, as in the measurement of potato or maranta starch grains the size is indicated by an arithmetical ratio \( (x) \). Thus under Amylum solani we find that "the error of asymmetry in length of the grain is given as \( 23\mu \) and is expressed as \( \bar{x} = 23\mu \). This means that after making the measurements of a large number of grains in a certain field the sum of the sizes of the grains divided by the total number examined gives \( x \), or the arithmetical ratio.

Again, in the study of starch grains the position of the point of origin of growth or nucleus is indicated by a fraction, the numerator and denominator indicating respectively the distance of the nucleus from the two ends or the two extremes of the longer diameter. Thus, \( \frac{1}{4} \) would indicate that the nucleus is central as in wheat starch; \( \frac{3}{4} \) as in the case of potato starch grains were the nucleus is one-fourth the diameter from the narrow end. In the case of maranta starch the position of the nucleus is given as \( \frac{1}{4} - \frac{3}{4} \), meaning that the nucleus is central or one-third the distance from the margin in longitudinal section.

In addition to the detailed descriptions of the macroscopic and microscopic characters of the drugs, assay methods are given for many of the potent drugs and statement giving the percentage of ash, amount of extractive, and also other special tests for identity or quality in certain cases.

**Chemical Substances or Medicinal Chemicals.** In most cases the formula of the chemical is given under the title. A purity rubric is not given, the descriptions and tests being so exact as to establish a high purity of the substance, as is generally the case with foreign pharmacopoeias. In the testing of chemicals for impurities, unless a special procedure is given, it is directed that three drops of the reagent shall be added to 5 Cc. of a solution of the chemical. Under Olea Pinguia are given a number of general tests for the testing of fixed oils and fats together with exact methods of procedure in determining the iodine number, saponification figure and acid equivalent. Under Olea Volatilia similarly a general procedure is given for determining the presence of alcohol or fatty oils. In some cases, as under Oleum Foeniculi, the optical rotation is given, and
again, as under Oleum Piperita, a method is given for the proximate constituent, as menthol. In determining the melting point of fats and fatty substances capillary tubes are used in which the fat is taken up by capillarity after it is melted and then allowed to stand for twenty-four hours, when the melting point is determined by using a glycerin bath. Specific gravities are determined at a temperature of \(15^\circ\) C. As would be expected \(0-16\) is taken as the basis for atomic weights, hydrogen being equivalent to \(1.008\).

**Pharmaceutical.**—The pharmaceutical portion of the book is characterized by the same originality and thoroughness as characterizes the parts already considered. In preparing vegetable drugs for grinding great care is exercised in the drying of the drug, none of the drugs ever being dried above \(50^\circ\) C. and those having volatile principles not above \(40^\circ\) C. and in some cases over quick-lime. They are then reduced to the fineness required and kept in ground-glass-stoppered bottles. Two kinds of sieves are used, one for coarse powders and the other for fine powders. In the sieves for coarse powders the meshes are round and are respectively in diameter \(1\frac{1}{2}, 3\) and \(5\) mm. These are designated as \(A_{1\frac{1}{2}}, A_{3},\) and \(A_{5}\).

For fine powders a sieve of silk is used, the meshes being square, there being \(10, 20, 30, 40\) or \(50\) meshes in one centimeter. These meshes are indicated as follows: \(B_{10}, B_{20}, B_{30}, B_{40},\) and \(B_{50}\). If in connection with an article no fineness is given for the powder, it is intended that the pharmacist shall use a powder of the general degree of fineness designated on pages 308 and 309. Again, there are quite a number of powders which are directed to be kept protected from light and these are indicated by asterisk (*). The physical factors which influence the quality or stability of drugs, as light, temperature, moisture, have been given careful consideration, and it is directed that all drugs and preparations not in daily use shall be stored in dark rooms, and in this connection we note that certain vegetable drugs as digitalis, are to be kept in tightly closed tin drums in which are placed wide-mouthed bottles containing burnt lime and covered with leather or parchment provided with a suitable number of perforations. It is also directed that hygroscopic substances shall be kept in containers with burnt lime. Volatile substances are to be kept in tightly closed glass-stoppered bottles. Chemicals which are affected by the light are required to be kept in black, red or yellowish-brown colored bottles. Extracts and ointments are to be kept in jars which do not permit the entrance of light and must be kept in a cool place. The commonly used terms relating to temperature in pharmaceutical processes and manipulations all have a definite meaning. Thus, when applied to water, luke-warm means a temperature of \(20^\circ-40^\circ\) C.; warm, a temperature of \(60^\circ-70^\circ\) C.; hot, a temperature of \(85^\circ-95^\circ\) C. Again, the temperature for the processes of maceration, digestion and infusion are respectively \(10^\circ-25^\circ\) C.; and \(90^\circ-98^\circ\) C.
In the weighing of drug materials three different grades of scales are directed to be used, which are designated as A, B, B₂. Scale A is used in weighing amounts of substances not exceeding 50 Gm., or 10 Gm with a finer scale. With this scale, which is known as a milligramme scale, the maximum declination or vibration should not be greater than two millimeters in one decimeter and not continue longer than one second when using a weight of 5 milligrammes. Scale B is known as a gramme scale and is used in weighing amounts not greater than 250 Gm. or 100 Gm. with a finer scale. With this scale the sensitiveness should be the same as Scale A, when using 50-milligramme weight. Scale B₂ is used for weighing amounts of substances not exceeding 1 kilogramme or 250 Gm. with a scale less sensitive than Class B. With this scale the sensitiveness should be the same as Scale A, when using a 250-milligramme weight.

Standard measures have likewise been adopted. A teaspoonful is defined as equivalent to 3 Cc.; a dessertspoonful as 8 Cc.; and a tablespoonful as 15 Cc., and physicians are requested to adopt the rule of using cubic centimeters when ordering liquid medicines. The standard dropper approved by the Brussels Conference has been made official; the dropper has a bore of 3 millimeters at the exit end and dropping 20 drops of distilled water at 15° C., which should weigh 1 Gm. A table has been included giving the number of drops in a gramme of various liquid preparations and solutions.

Fifty-five of the articles official in the third edition were deleted, and 195 new articles were added, making a total number in the fourth edition of 652. Of these about 210 are required to be kept in stock at all times by the apothecary. The remaining 442 articles are indicated by a plus (+) sign. In accordance with the Brussels Conference, as already pointed out, the strength of tinctures of potent drugs is 10 per cent. Acidum hydrocyanicum dilutum, 2 per cent.; aqua laurocerasi, one-tenth of 1 per cent., or one part in one thousand, of hydrocyanic acid. The different narcotic extracts and fluidextracts and liquor kalii arsenicosi, 1 per cent.; pulvis ipecacuanhæ opiatus, 10 per cent. of each of the potent drugs; sirupus ferri iodati, 5 per cent.; vinum stibiatum, four-tenths of 1 per cent., or 4 per thousand. In order that physicians as well as apothecaries shall have in mind the changes in strength of the preparations of potent drugs, the abbreviation F. I. (formula internationalis) is placed after the title.

In a table (Table A) a list of 42 poisons is given which should be kept in a closet to themselves. In another table a list of poisons is given which may be kept out convenient for use when marked by a label bearing a distinct blue cross. Another table includes medicines which physicians are required to keep on hand.

Thus with the number of drugs and preparations which the pharmacist must always have on hand and those which physicians are required to keep at hand the interests of the public are looked after in a manner which it seems to me is very commendable.
**Doses.**—In order to satisfy the expressed wish of most of the apothecaries of Holland who desired to have a guide that they might follow, compounding prescriptions containing potent substances, the single maximum dose and the maximum dose in twenty-four hours for an adult are given, these being given also in the index, which is in fact an alphabetical table giving in addition information regarding solubility in water and alcohol and indicating the drugs which are to be kept away from light and those which are to be kept in hermetically sealed containers. If a physician desires to use a larger dose, he is expected to indicate the fact by placing an exclamation point ( ! ) after the name of the medicine specified. These doses hold not only for substances when intended for internal administration, but also when administered hypodermically, used in suppositories or applied to the skin.

**First help tables.**—In order that the pharmacist may be prepared to act in cases of sudden poisoning there is given in the Appendix an outline of procedure and a list of suitable antidotes which may be easily dispensed by him, he being required to summon a physician as soon as practicable.

The appendix comprises some eight or nine tables, including (1) General Reagents, (2) Volumetric Solutions, (3) a table of solutions of the alkalies and mineral acids giving the specific gravity, amount of the chemical in 1000 cubic centimeters, and the titration equivalent for each cubic centimeter. (4) A table giving the specific gravity of certain substances at temperatures between 12° and 35° C., as alcohol, ether, chloroform, mineral acids, etc.; (5) A table giving the number of standard drops in a gramme of various potent drugs; (6) an Alcohol Table; (7) A Saturation Table; (8) A Neutralization Table showing the amount of alkali necessary to neutralize acids or of acids to neutralize alkalies; (9) A table of atomic weights of the common elements.

While it would be desirable for some reasons to compare formula with formula and description with description of the Netherlands and our own Pharmacopoeia this is manifestly impracticable, even with the many important ones, in a paper of this kind. I will, however, consider a few of the interesting features.

Not only has the Netherlands Pharmacopoeia adopted the standards of the Brussels Conference for tinctures of potent drugs but also for certain alkaloids, as the Hydrochlorate of Cocaine, the title of which is Hydrochloras Cocaini, F. I. which means that it shall answer the original MacLagan's test for other coca alkaloids, and in addition to other tests there is a method given for the detection of cinnamyl eegonine.

Under the various galenicals, as tinctures, various data are given for their identification and test of purity, as color, specific gravity, amount of extract, and certain specific tests. In the preparation of tinctures, unless a special method is given, either percolation or maceration may be used. When maceration is followed, the comminuted drug is mixed with the
proper quantity of the menstruum, allowed to macerate five days with occasional agitation and protected from light. The marc is pressed cut and the liquid portion allowed to stand in a cool place for two days, when it is filtered, care being taken to prevent evaporation. In following out the percolation method the menstruum is divided into three parts, two of which are intimately mixed with the drug, and allowed to macerate for twelve hours. This macerated mixture is then added to a percolator and slightly compressed. Sufficient menstruum is added until the percolate begins to flow from the orifice of the percolator, the latter is then closed and the drug allowed to macerate for 24 hours. The stopper is removed and percolation allowed to proceed, and as much menstruum added as is necessary to make the required amount after expression of the marc. The tincture is allowed to stand for two days in a cool place, when it is filtered, taking care to avoid any loss through evaporation.

All of the tinctures of potent drugs are made by percolation, while all of the remaining tinctures are made by maceration. In the case of Tinctura Secalis Cornuti and Tinctura Strychni the fixed oil is first removed from the drugs by means of petroleum ether. There is a general test given for the detection of wood alcohol and acetone in tinctures.

Three classes of extracts of vegetable drugs are recognized: dry extracts or Extracta Sicca which contain not more than 6 per cent. of moisture: solid extracts, or Extracta Spissa which contain not more than 20 per cent. of water, and liquid extracts. The extracts of potent drugs are made by percolation in much the same manner as given for tinctures, the alcohol being removed either by distillation at a temperature not higher than 90° C., or it may be allowed to evaporate spontaneously until the extract has the desired consistency. Most of the extracts of the other drugs are made by maceration or infusion, it being understood that the processes are carried out at definite temperatures, considerable care being directed in the evaporation of the extracts. In Extractum Secali Cornuti chloroform water is used as a menstruum; in a number of extracts a certain amount of glycerin is directed, as with cinchona. With the latter drug dilute hydrochloric acid also forms a part of the menstruum. Methods are given for the determination of moisture, the examination of the ash for metallic substances, and they are required to be protected from light, and in view of their containing soluble constituents, to be kept in glass-stoppered bottles.

It is rather surprising that in view of the increasing use of so-called animal drugs in this country, as antitoxins, etc., none of these articles are official in the Netherlands Pharmacopoeia. This is probably accounted for by the fact that one of the principles of revision is not to include any substance, no matter how widely used it may be, which the pharmacist does not prepare or has no adequate means of testing. Neither are patented or trade-marked preparations official, the entire responsibility for
their quality resting with the manufacturer. On the other hand, formulae are given for the preparation of teas (species), artificial aperient salts, as Carlsbad salts; medicated cottons and gauzes; granules, and so on. Indeed there are methods for every class of pharmaceutical preparations from Aquæ to Vinæ, and with standards or tests for every substance and preparation used. Everything that science or experience can offer is at the disposal of the physician, and the pharmacist can not misunderstand the specifications of the physician or fail to supply uniform and efficient preparations.

I may in conclusion say that the Netherlands Pharmacopœia is not only a very valuable practical guide for the retail pharmacist but that it furnishes high standards for the official drugs, the revisers having availed of the scientific progress touching their work and having also manifested a broadly democratic spirit. We have also in the Netherlands Pharmacopœia a standard, which while revised by authority of the Government, yet strictly speaking none of the members of the Commission are Government officials. The Commission is a small one, and the members are directly responsible for the work, which while it serves as a guide for the pharmacist, is clearly for the protection and benefit of the people.

The Japanese have used it as a model since 1880, and it would be well if an English translation were available for consultation and study in this country.

Finally, I acknowledge my indebtedness to Mr. Peter Amsterdam for assistance in translating and critically examining certain portions of the Latin edition. I have also had access to two excellent reviews of this work, one by Schoepp in the Apothecker Zeitung for 1906 and 1907, and another by Weigel in the Pharmaceutische Zentralhalle for 1906.

The Chair said he thought Mr. Kraemer certainly deserved the thanks of the Section for this very instructive paper, as he had taken a great deal of pains with it. He wanted to point out particularly that the Netherlands Pharmacopœia differed from the others somewhat, in that in contained a chapter on antidotes. He commended this idea as an excellent one, and as one which would be of great service to the pharmacist when hastily summoned to give relief in an urgent poison case.

Thereupon Mr. Hallberg moved that this Section request of the Association in general session that it recommend that a chapter on antidotes, similar to that of the Netherlands Pharmacopœia, be published in the next edition of the U. S. P.

This motion was seconded and carried.

The Scandinavian Pharmacopœia, covering the countries of Denmark, Sweden, and Norway, was presented in verbal abstract by Mr. Hallberg, the full text of his paper to be submitted later.*

* Unfortunately Prof. Hallberg failed to prepare the paper, and his subsequent illness and untimely death have prevented a continuation of his labors.
Mr. Wilbert said the Danish Pharmacopoeia was perhaps the only one that complied absolutely with the Brussels protocol. He thought this was the only Pharmacopoeia that directed that opium preparations be made by percolation, and gave in detail the process. The Austrian and one or two others gave directions that opium should be made by percolation, but did not give directions.

A paper upon the Spanish Pharmacopoeia was read by title and referred. The full text here follows:

A GLANCE AT THE FARMACOPEA ESPANOLA, VII.

BY HUGH CRAIG, NEW YORK.

Early in one's acquaintance with the seventh edition of the Spanish Pharmacopoeia he is impressed with its blending of progressiveness and mediævalism. As evidence of the progressive element among the profession in Spain there is the official sanctioning of a process for preparing "bromo-formo" and another for "aristol" and the fixing of a standard for anti-diphtheritic serum; that the pharmacy of the past still survives in that country is shown by the official recognition of snails as a demulcent, and soot as a vermifuge. Truly the revisers succeeded in their expressed desire to harmonize tradition and progress.

The revision of the Spanish Pharmacopoeia is undertaken at irregular intervals by a permanent commission appointed by the Royal Academy of Medicine. There were seven members of the commission which prepared the present edition; all use the title "Doctor" but I believe four of them were pharmacists. The work of revision was begun in 1903; and the revised pharmacopoeia received the royal approval, June 21, 1905. All such new medicinal agents were added as had proved, in the experience of the clinic of the academy, useful in the present-day demands of therapy, and whose real composition and mode of preparation were not secret.

Each material is concisely described, the chief characteristics by which it may be identified being clearly stated. The descriptions of vegetable drugs are particularly good; and in several instances the more common adulterants are named. For aloes, catechu, wax, and most of the gums and resins identity tests are given. There are few purity rubrics, but each chemical agent is required to satisfy several given tests as to its purity. Statement is also made of the chief microscopic characteristics of calamus, cascara sagrada, catechu, cinchona, cinnamon, conium fruit, coriander, cotton, elemi, fennel fruit, granatum, honey, ipecac, lycopodium, musk, oleoresin of male fern, opium, phellandrium, pine tar, pyrethrum, quassia, quebracho, starch, storax, tea, and tolu. An ash-limit of 10 per cent. is fixed for asafetida; and one of 6 per cent. for cochineal.

In the prologue it is stated that the process of manufacturing medicinal chemicals is given in the case of those which may not be more advantageously prepared in large quantities and those which require especial
care in their preparation for medicinal use. Some of the official processes are those for acetic acid, gallic acid, hydrochloric acid, nitric acid, phosphoric acid, monobromated camphor, absolute alcohol, chromic anhydride, quinine alkaloid, sodium and potassium tartrate, and a number of the newer organic medicinal chemicals. The pharmacist is advised to test all chemicals purchased, and there are official processes for purifying sulphuric acid, sodium borate, sodium chloride, ether, mercury, and several other "heavy" chemicals. The atomic and molecular weights are based on the International Table for 1904; as 16 is taken as the weight of oxygen, the official figures differ from those of the U. S. P. A wide variation frequently exists between the figures of the F. E. and those of the U. S. P. for solubilities and melting points; although the solubility figures of the F. E. are computed at a lower temperature (15° to 15.5° C.) they frequently vary inversely from those of the U. S. P.

The standards of the Brussels Conference of 1902 for preparations of potent drugs have been adhered to quite generally. All formulas must satisfy the Commission pharmacetically and pharmacologically before they are made official. Much space has been saved through the use of type-processes for the various groups of galenicals.

At the end of the article under each title—in such cases as the substance or preparation is per se a medicament—are given the therapeutic uses, manner of employing, and the doses for an adult, the pharmacopoeia being considered as necessary to the physician as to the pharmacist. When a doubt exists as to the value of a medicament the statement of its therapeutic use is qualified by the words "recommended for the treatment of," etc. The doses are given only in the metric system, drops being stated in the equivalent fractions of a gramme.

The nomenclature of former editions has been retained as more intelligible to those who use the pharmacopoeia (to quote from the prologue). It certainly is puzzling to the foreign user to find solution of ammonium acetate and solution of lead acetate among the "acetatos"; solution of potassium sulphide under "sulphuro"; solution of potassium arsenite among the "solucions"; tincture of iodine in the same group; poppy capsules and leaves under "adormidera"; poppy petals as "amapola"; "aristol" as an official name, and "salol" as a synonym. The Spanish seem to have recognized the possibilities of the coined name, and among the official Spanish titles one meets—in a slightly changed orthographic dress—such old friends as "creolina," "euforina," "exalgina," "eucuinina," "fenacetina," "formol," "ictiol" (The English name ichthyol is given as a synonym, and the substance is allotted the formula C_{28}H_{36}S_{2}O_{6}[NH_{4}]_{2}, "sacarina," "sulfonal," "trional," "uretano," "vaselina," and "zeroformo."

In former editions of the F. E. the materia farmacéutica and the preparaciones farmacéuticas were given in two separate parts of the book.
They have now been united in alphabetical order, following the general custom. The first part of the present edition is devoted to a number of tables of weights and measures, specific gravities and their comparison with percentage solutions, alcohol dilutions, drops in a Gm. of official liquids, etc., and a list of reagents and clinical and volumetric solutions.

Percolation is directed in the processes for many of the extracts and tinctures, for compound syrup of sarsaparilla, and for oleoresin of male fern.

First in the list of "preparaciones y materiales farmacéuticas" is "aceite alcanforado," the oft-troublesome camphorated oil. Oleum camphoratum is the official Latin name, and linimentum camphoratum is the synonym. The formula calls for 10 Gm. of powdered camphor in 90 Gm. of olive oil, to be heated on a water-bath in a stoppered container. Only the fixed oils or the medicated oils made by infusion or otherwise with a fixed oil base are known as "aceites." Some of the infused oils are polypharmacal wonders; one "oleum stramonii compositum," contains eighteen ingredients besides the base. There are two phosphorated oils: 1 in 100 for external use; the other for internal use a 1 in 10 dilution of the first.

Benzolic acid it is directed to be made from benzoin. No source of salicylic acid is given; neither is there an official process. Potassium ferrocyanide and sulphuric acid are used in the preparation of "acidum cyanhydricum medicinale," a 2 per cent. solution of HCN. There are two diluted sulphuric acids, one alcoholic of 25 per cent. strength; the other a 10 per cent. solution in water.

"Aconitum" includes both the root and the leaves, although only the root is used in the preparation of the extract and the tincture. Under the official title quite frequently more than one part of the plant is included, e.g. the leaves and seeds of hyoscyamus; the root and leaves of belladonna; the seed and fruit of the pumpkin; strawberries and their root; and the fruit, leaves and flowers of bitter orange. Generally but one of the parts enter into an official preparation: not so with arnica and hamamelis, both the flowers and root, and the bark and leaves, respectively, being used in the official tinctures of these drugs. Cacao butter differs from coco butter which is coconut oil. "Sanguinaria" is the inflorescence of paronychia argentea, a member of the four-o'clock family.

Among the "aguas" are carbonated waters, cologne waters, eleven distilled aromatic waters, albuminates water, "aqua calcis," "aqua chlorii," "aqua fenicata" (2 per cent.) "aqua nitrogenata," "aqua oxigenata" (10 volumes), "aqua saturata oxigeni," "aqua alba" (lead water), distilled water and sterilized water—this latter being used chiefly in the preparation of solutions for hypodermic injection, several such being official.

Formulas are given for two embalming fluids.

Absolute alcohol, 95 per cent. alcohol, and 60 per cent. alcohol are
official, although 70 per cent. alcohol is most used as a menstruum. There are also a number of aromatic alcohols or spirits of from two to fifteen component parts.

Cottons, plain, purified and variously medicated receive official recognition. Processes are given for preparing the latter as well as for several medicated gauzes.

"Ammoniacum" is the official Latin name for an aqueous solution of NH₃ made through the interaction of ammonium chloride and lime. The strength is 22 degrees Baume, specific gravity 0.923.

The metals, antimony, bismuth, gold, iron (in three forms), lead, mercury, silver, tin, and zinc are official. Tin and iron are used *per se* as remedial agents.

The official "aristol" (synonyms "diiodothymulum" and "thymolum biiodatum") is made through the interaction of iodine 60, potassium iodide 80, in distilled water to make 300; and thymol 15, sodium hydroxide 15, in distilled water to make 300.

"Linimentum saponis camphoratum" is a synonym of "balsamo opodeldoch liquido," containing olive oil soap 10, camphor 9, solution of ammonia 4, oil of rosemary 2, oil of thymol 1, and 80 per cent. alcohol 100, "balsamo opodeldoch solido" contains lard soap 12, camphor 10, the same quantities of solution of ammonia and essential oils as the liquido, and 100 parts of 90 per cent. alcohol.

"Candelillas" or bougies are made with a base of glycerin, honey, sugar of milk, and acacia, and are coated with isinglass. Three formulas are official. There are three official ovules with a glycero-gelatin base; one glycero-gelatin suppository of rhatany; one of plain cacao butter; and one of aloes and sodium chloride with a base of evaporated honey.

Starch capsules are officially described. Formulas are given for making gelatin capsules of three textures, for liquids.

Cataplasms of linseed meal and of bread and lead are official, but there is no clay poultice.

"Cerato simple," F. E., is a mixture of almond oil and white wax. "Cold cream" is a synonym for "ceratum spermatis coeti," which contains almond oil, rose water, white wax and spermaceti. "Ceratum galeni" is an admixture of almond oil, rose water and white wax. The "pomadas" are almost identical with the ointments of the U. S. P. The bases are lard, alone, and with wax, suet, glycerin or almond oil, and vaselin. The last-named is used as the base for potassium iodide. Lard and glycerin form the base for the pomade of iodine and potassium iodide, which contains 4 per cent. of each substance. The "unguentos" are polypharmacal preparations, the bases being various mixtures of lard, wax, olive oil, suet and resin. "Ungüento de artanita compuesto" contains aloes, asafetida, sodium chloride, scammony, jalap, chamomile, resin, artanita, wax, lard and olive oil. It is recommended as a purgative for children, to be applied with friction to the abdomen.
Mercurous chloride is official in three forms—precipitated, sublimated and vaporized.

“Creolinum” is described as a preparation of the heavy oil of coal tar and an oleo-resin soda soap; no process is given for a similar preparation. Cresol is official.

The official standard for diastase requires that, when mixed with 60 times its weight of starch in a 6 per cent. paste and heated for 6 hours at 50°C. it should form a liquid which will pass readily through a filter and decolor five times its volume of normal cupro-potassic liquid.

Pancreatin—also called “trypsina”—in a one-half of 1 per cent. aqueous solution, neutralized with sodium bicarbonate is required to dissolve 100 times its weight of coagulated and shredded albumin in 6 hours, at a temperature of 40°C. By the starch test the standard is 1 to 300.

A process is given for making peptin from the rennets of sheep or calves, or the stomachs of hogs. The digestive power required is 1 to 10 of dried fibrin, in an acid medium.

There are official formulas for three ophthalmic gelatin discs.

As examples of medieval pharmacy, the “electuarios” stand well to the front. “Discardio” contains eleven ingredients in honey of roses.

“Theriaca” (theriaca) has fifteen aromatic and medicinal constituents in a vehicle of honey, wine, and honey of elder.

Fifteen plaster masses are official, the bases being several, and the ingredients of some being many. Five sparadraps receive official recognition. Cantharides plaster must be spread on red cloth.

Irish moss is the agent directed for emulsifying cod liver oil. No sugar is used in the emulsions of this oil, which contain 12 per cent. glycerin.

In the articles on the essential oils particular attention is given to their physical characteristics and their reaction with iodine. When they are optically active the fact is stated only in the general terms, dextrogyrate or levogyrate.

“Spiritus nitri dulcis” is a mixture of alcohol 60, and nitric acid 20.

“Liquor anodynum mineralis Hoffmanni” is the Latin synonym for a mixture of ether 80, and alcohol 20.

Of extracts there are three sorts—aqueous, alcoholic and ethereal. The first-named are officially described as of the consistency of “a pill mass or a soft extract.” Aqueous extract of opium is a powdered extract and should assay 20 per cent. of morphine by the process given for opium. The tincture of opium is prepared from the extract with 70 per cent. alcohol. The consistency of the alcoholic extracts should be such that they “will not adhere to the fingers when cold.” The alcoholic extract of nux vomica is a powdered extract, which should assay 16 per cent. of alkaloids by the following method:

Five grams of the extract are dissolved in 30 grammes of water made alkaline with a slight excess of sodium carbonate. This solution is shaken
with 10 grammes of chloroform; the chloroform layer decanted and shaken with water acidulated with sulphuric acid; the aqueous acid liquid is decanted; to it is added solution of ammonia in excess, and it is then shaken with 15 grammes of chloroform. The chloroform layer is separated and evaporated, and the residual alkaloids weighed.

Fluidextracts are scarce in the Spanish Pharmacopoeia. Two only are official: hamamelis and hydrastis, each a 1-in-1 hydro-alcoholic liquid, containing 10 per cent. of glycerin. "Extractum fluidum rhamni pushani" is a synonym for the alcoholic extract of that name, a 10-in-3 solid extract.

In making Blaud's pills it is directed to triturate first the potassium carbonate with the ferrous sulphate until a soft paste is procured. A solution of ferrous iodide is prepared as the first step in making Blancard's pills; honey is added to this and the mixture evaporated. Then the pills are made by adding dry excipients.

The official "tabletas" are lozenges with a base of sugar and tragacanth.

Four basic soaps—almond oil, olive oil, cocoanut oil and lard—are official; all are soda soaps. There is no official soft soap. Three medicated hard soaps are official.

Sweet medicines appeal to the Spaniard. He puts sugar in his decoctions, and he has fifty official syrups. The medicinal ingredients of these range from acacia to strychnine sulphate, including iron arsenate, iron iodide, codeine, belladonna, opium, ether, and mercuric-potassium iodide. "Simple" syrup contains but 64 per cent. of sugar. In making syrup of tolu, the tolu is digested in the water at 60°, and the sugar dissolved in the decanted liquid.

Two solutions of magnesium citrate are official. They are called "limonadas purgantes;" one is not effervescent.

"Linimentum ammoniacale" is a mixture of 10 parts of solution of ammonia, and 50 parts of olive oil. "Linimentum oleo-calcicus" contains 35 parts of almond oil, and 65 parts of lime water. Most of the preparations known as liniments will be found elsewhere than in the "linimento" group.

The official requirement for opium is that it contain 10 per cent. of morphine. The assay process is as follows: Triturate 15 grammes of opium with 8 grammes of recently slaked lime; place the mixture in a capsule with 150 grammes of distilled water and heat to 50° or 60° C. for two hours, stirring and replacing the water lost by evaporation. Filter the mixture when cold, and retain 106 Cc.; add to this 25 Cc. of ether and 3 grammes of ammonium chloride, agitate gently; set aside for 3 hours; decant the ethereal layer; shake out the residue twice with ether; mix the ethereal liquids; set aside for 12 hours; collect the precipitate on a filter; wash container with water; dry the precipitate at 95° C.; wash out the narcotine with chloroform; and weigh the morphine remaining. If any
more than 0.92 Gm. of morphine is obtained by this process the opium assayed may be considered standard.

Dover's powder is made with a diluent of equal parts of potassium nitrate and potassium sulphate. The strength is the same as that of the U. S. P. preparation.

Ipecac is required to contain 2 per cent. of alkaloids, and guarana, 3 per cent. of caffeine. The official jalap must contain from 15 to 18 per cent. of resin. No assay process is given for any of these.

Nux vomica is standardized at 2.5 per cent. of alkaloids, but no assay process is given. The tincture is made from the powdered drug.

Three species of cinchona are recognized: cinchona calisaya, 2.5 to 3.5 per cent. total alkaloids, principally quinine; cinchona officinalis, 2 to 3 per cent. total alkaloids, principally cinchonine; and cinchona succirubra, 2 to 3 per cent. total alkaloids, principally quinine. Microscopic descriptions are given but no assay processes.

The source of the official alkaloids is seldom given, a noticeable exception being in the case of sparteine from spartium scoparium.

Solution of hydrogen dioxide is standardized by collecting and measuring the volume of the oxygen freed by the action of sodium hydroxide and manganese dioxide on the solution.

There are official methods for standardizing cherry-laurel water, and for detecting saccharin in sugar.

Anti-diphtheric serum is official in 2 forms: liquid, with a minimum content of 200 Ehrlich antitoxic units in each cubic centimeter; and solid (powder or scales) made by evaporating the liquid in a vacuum at 20° to 25° C. It is not lawful to employ serum other than that made in laboratories licensed by the government.

There are five official aqueous tinctures, varying in strength of the medicinal constituent from 1 per cent. to 3 per cent.; thirty-nine hydro-alcoholic tinctures, whose menstrua contain from 60 to 90 per cent. alcohol; a 1-in-1 chloroformic tincture of cantharides; and three ethereal tinctures.

The vinegars of the Spanish Pharmacopoeia are made with wine vinegar, fermented or distilled. The medicinal wines have as menstrua various native wines, a number of which are official; so too are coffee, tea and cacao beans, but not extract of malt or any spirituous liquor.

"Acetum opii compositum" represents 50 per cent. of opium, with saffron and nutmegs. "Vinum opii compositum" (Laudano de Sydenham") represents 10 per cent. of opium, with cinnamon, cloves and saffron.

These are the essentials of the seventh edition of the Spanish Pharmacopoeia from the viewpoint of one who is not a user of the book. Perhaps had I an acquaintance with the inside workings of a Spanish pharmacy my viewpoint would experience a change of location.

The Chair remarked that the Spanish Pharmacopoeia was the poorest in Europe.
"The paper upon the Pharmacopoeias of Spanish America" was the title of a paper by M. I. Wilbert, and Mr. Wilbert presented his subject as follows:

THE PHARMACOPOEIAS OF SPANISH AMERICA.

BY M. I. WILBERT.

Largely, perhaps, because of the inherent self-conceit which is such a predominating characteristic of the Anglo-Saxon people we "Real Americans" have essayed to prepare for the less favored inhabitants of Spanish America a translation of our admittedly excellent Pharmacopoeia; and some, if not all of us, may perhaps feel disappointed, should this translation not meet with the immediate and widespread acceptance in the countries to the south of us that we think it deserves.

In view of these, our expectations, it may be advisable to point out some of the reasons why we should not be over-sanguine in this regard, and why we should be content to consider the Spanish translation of the U. S. P., as something in the nature of legitimate Home Missionary work, rather than a much desired pharmacopoeial ideal for the Spanish American people with whom we have as yet little in common.

We should also not forget that members of the Board of Trustees, who were more directly concerned in the publication of the Spanish Edition of the U. S. P. were particularly desirous of supplying an acceptable book for the Spanish-speaking sections of the United States, for our recently acquired Insular possessions and for Cuba, our Island neighbor, whose trade interests naturally bring its people into close touch with the people of the United States.

The remaining Spanish American countries have much less in common with us, at the present time, and it would be folly indeed to expect that any one or all of them would be likely to adopt or follow either our Pharmacopoeia or our pharmaceutical methods and practices.

To illustrate the reasons for this assertion it will suffice to call attention to the fact that the practice of pharmacy in Central and South America is generally based on Continental usages and not on the practices now in vogue in English-speaking countries.

The Pharmacopoeias of France, Spain and Germany, about in the order named, have been, and still are, widely used throughout Spanish America and naturally they have left their impress on the several Spanish American Pharmacopoeias that are now available.

So far, there are four well-known Spanish-American Pharmacopoeias: The Pharmacopoeia of Mexico, of which the fourth edition was published in 1904, the Pharmacopoeia of Venezuela, published in 1898, the Pharmacopoeia of Argentine, published in 1898, and the Pharmacopoeia of Chili, published in 1886. All of these several pharmacopoeias are interesting, and all present some more or less unique features.
THE PHARMACOPOEIAS OF SPANISH AMERICA.

THE PHARMACOPOEIA OF CHILI.

The Pharmacopoeia of Chili, the oldest of these several Pharmacopoeias, is evidently an elaboration of the German Pharmacopoeia II, was compiled in Chili by Adolfo Murillo and Carlos Middleton, and printed in Germany, by F. A. Brockhaus, Leipzig, 1886. The book contains a total of xii and 457 pages, 8vo., and the descriptions and formulas are arranged alphabetically according to the Spanish titles.

Each class of drugs or galenical preparations is prefixed by a class title and in connection with galenical preparations, general methods of procedure are also given.

The total number of titles in this Pharmacopoeia aggregate 724, including 52 general headings or definitions, 191 crude drugs, 167 chemical substances and 314 galenical preparations.

An appendix contains a table giving maximum, single and daily doses of potent medicaments, also a table enumerating the several class-headings, and preparations with page reference and a special index showing the available preparations of each official drug.

The descriptions are graphic and concise, and include tests for identity and purity, directions for preserving and some reference to therapeutic uses.

THE PHARMACOPOEIA OF ARGENTINE.

The Codex Medicamentarius or National Pharmacopoeia of Argentine, both in size and in the arrangement of some of the contained material suggests the influence of the French Codex, though the descriptions and requirements indicate some degree of German influence.

The now official, first edition of this book was published in Buenos Aires, in 1898. It was compiled by a Commission appointed by the Chief of the National department of Hygiene, which department was by law authorized to undertake the preparation of a National Pharmacopoeia, and each copy contains a number of the order and the seal of the National Department of Hygiene as a guarantee of the authenticity of the book. This Pharmacopoeia comprises a total of x and 790, large 8vo., pages. The book is printed in Spanish, and the articles are arranged alphabetically according to the Spanish titles. No less than 509 pages are devoted to the official descriptions of drugs, 30 pages to reagents, 42 pages to tables and 100 pages to a double column index.

The index is somewhat of an innovation in that it gives the official Spanish title in heavy-faced type, the Latin name in Italics and other references, including synonyms in Roman type, cross references appearing throughout.

The Pharmacopoeia of Argentine includes a total of 742 titles, or 14 general headings, 145 crude drugs, 195 chemical substances and 388 galenical preparations. The descriptions and definitions are rather comprehen-
sive. They include descriptions of the microscopical characteristics of drugs, chemical tests for active principles and possible contaminations, solubility factors, physical properties of galenical preparations, therapeutic uses of various substances and doses.

The appendix contains general directions for conducting the several tests and comprehensive tables showing equivalent weights and measures, equivalent degrees of temperature in centigrade, Réaumur and Fahrenheit scales, the influence of temperature on the specific gravity of a number of official substances and a table giving the solubility of official chemical substances in cold and in hot water, also in alcohol, ether, chloroform and glycerin.

THE PHARMACOPEIA OF VENEZUELA.

The Pharmacopœia of Venezuela also evidences the influence of the French Codex, which was, formerly, the legally recognized national standard. The "Farmacopea Venezolana," approved by the medical council of the Republic as the Pharmaceutical Codex of Venezuela, was compiled by Francisco A. Risquez, and published at Caracas, in 1898.

The prologue discusses the need for a National Codex, and points out that while the desirability of complying with other national standards was fully recognized the Pharmacopœia of the United States and the Pharmacopœia of Great Britain are not well suited for this purpose, as they do not provide for the use of the metric system as usually followed in Venezuela and other Spanish American countries.

The Pharmacopœia of Venezuela contains a total of xxi and 466 pages 8vo., and includes some 795 pharmaceutical titles: 52 general headings, 292 crude drugs, 118 chemical substances and 333 preparations.

The book is divided into four parts: Preliminary notices, simple substances, galenical preparations, and miscellaneous.

The first part contains a description of weights and measures, thermometry, specific gravity and a number of tables: among others, a table of solubilities in water and alcohol, and a table of maximum, simple and daily doses of potent medicaments, a list of incompatibilities and a list of reagents and volumetric solutions.

The second part contains descriptions of simple drugs, including chemicals. The monographs are quite comprehensive and include physical and chemical characteristics, properties and uses and doses. The articles are arranged alphabetically according to their Spanish titles, Latin names appearing only as synonyms.

Part three, devoted to galenical pharmacy, is prefaced by a general description of pharmaceutical operations including calcination, distillation, evaporation, filtration, lixiviation, maceration, sublimation, etc.

The official formulæ are divided into classes, and each class is accompanied by a concise definition. Extracts and fluidextracts are presented
in tabulated form giving the name of the drug, the part employed, the menstruum to be used, and in connection with extracts, the amount of resulting product from 1000 Gms. of the drug used.

Part four contains a description of mineral waters, a compilation of the laws of Venezuela relating to Pharmacy and Medicine, a list of articles allowed to be sold only on prescription, a list of proprietary preparations approved by the Medical Council and an index.

The most radical innovation, however, so far as National Pharmacopoeias is concerned, is to be found on the advertising pages, some ten in number, evidently utilized as a source of revenue. They are taken up by the announcements of local pharmacists and advertisements of French proprietary specialties.

THE PHARMACOPEIA OF MEXICO.

The Mexican Pharmacopoeia, the largest, and in many respects the most comprehensive of the Spanish American Pharmacopoeias is of unusual interest, because it is the only one revised or issued since the meeting of the International Conference at Brussels, in 1902.

This Pharmacopoeia was first published in 1874, and the present fourth edition, was published in Mexico in 1904, under the auspices of the Pharmaceutical Society of Mexico. The book was revised by a Committee of seven and is decreed to be official in the Federal District and in the Territories. The general characteristics of this Pharmacopoeia have been reviewed by Mr. Mayo, and I desire to call attention only to some of the more specific features which serve to illustrate the influences that have dominated pharmacy and medicine in Spanish America. Like the Pharmacopoeia of Venezuela, that of Mexico is also based on the earlier editions of the French Codex. It is divided into parts: the natural products, chemical substances and pharmaceutical preparations being classified separately, the articles being arranged alphabetically, according to the Spanish titles.

In the new Fourth Edition the Protocol of the Brussels Conference has been closely adhered to, even to the inclusion of the normal drop-counter. Regarding this later innovation, the introduction says: "In pharmaceutical practice measures of capacity should not be used, but all medicaments, in general, should be weighed. When it is necessary to measure by drops any small quantity of liquid use should be made of the Normal drop counter prescribed by the Brussels Conference."

The remaining pharmacopoeias that are authoritatively recognized in Spanish American countries, are the Spanish and the French, both of which have the general characteristics that appear to appeal to pharmacists in Latin America.

The Spanish Pharmacopoeia has the official articles arranged alphabetically according to the Spanish titles, while the Codex is arranged according
to French titles. In this connection we should also remember that in the greater portion of Spanish America, the French language is quite as familiar to educated people as is the Spanish.

The German Pharmacopœia, while it appears to be well-known throughout South America, largely because of the ubiquitousness of the German Apotheker, has nevertheless failed to make much of an impression on local conditions. It is used as a reference book, and is appreciated because of its merits, but it is not popular, and so far as known, has not been adopted by any one of the South American countries as an authoritative standard.

From the evidence presented, it would appear that pharmacists in the greater portion, at least, of Spanish America, have been trained in the Continental method of weighing liquids, and do not take kindly to the use of measures of capacity.

They are thoroughly familiar with metric quantities and metric equivalents for English weights and measures, including our “approximate measures,” do not appeal to them.

They are habituated to the use of Spanish or French titles, and do not appear to require the Latin names; therefore, do not take kindly to a book arranged alphabetically according to Latin titles.

They have learned to appreciate general formulas and class descriptions as given in the Codex, and would no doubt require a continuance of such descriptions in any book of this type that is to be used at all widely.

From what has been said we should not infer that because the pharmacists of Spanish America are not inclined to accept our ideas and opinions regarding pharmacopœias and pharmaceutical practices they are in any way lacking in professional spirit or training.

The late Nicholas Senn, in his “Travel Notes from South America,” clearly points out that the medical and pharmaceutical professions are well established, and are largely made up of men who are thoroughly well equipped and who stand high in their respective communities. By training and affiliation they have much more in common with people of Continental Europe than they have with us. In many ways they are more cosmopolitan and less hampered by local prejudices than are we in the United States.

In conclusion, I would reiterate the belief that the publication of the Spanish edition of the U. S. P. will have a broadening influence on American pharmacy in that it will tend to bring our Pharmacopœia more directly in competition with the corresponding standards of Continental Europe, and will thus serve to expose the shortcomings of our ideas and practices in a way that could never be done at home.

Mr. Mayo said he had been told by a member of the Association, a resident of Porto Rico, that the U. S. P. was adopted by Costa Rica long before it was presented in the Spanish language.

Mr. Wilbert said that in Costa Rica a number of pharmacopœias were
adopted as official, and among them the U. S. P. The French Codex was also official there. In Cuba, however, the U. S. P. was the official and legally recognized standard. The Cuban Government, some two years ago, had adopted the U. S. P. as the official Pharmacopoeia of the island of Cuba. The Spanish translation was in use now, and was also being introduced in the Philippine Islands. He thought it would be very interesting to see whether American practices would be used in connection with the Pharmacopoeia, or the Pharmacopoeia used in connection with European practices.

The Chair told of the incident of a Spanish translation of the U. S. P. lying upon the counter in his store being picked up by a South American, who was so impressed with it that when he returned to Montevideo at the end of February or the first of March, he took a copy with him, and promised to popularize the United States Pharmacopoeia in Uruguay.

Mr. Mayo said it might be interesting to the members to know that the U. S. P. was selling steadily all over South America. The sales were by no means confined to Cuba and Porto Rico. Some sales had been made in the Argentine Republic, and a good many on the west coast of South America, and the sales had been quite steady. The sales during the last three months had nearly doubled the sales of the previous three. It was feared, after the sales of the Spanish translation dropped off after the first six months, that the demand had been supplied, but the sales of the past three months indicated renewed interest. It was also gratifying to note that these sales were quite general, practically all over South America, and especially on the west coast.

Mr. Wilbert thought one reason for this was the really excellent way in which the book had been translated. Spanish scholars were universal in their praise of the translation of the U. S. P. The language was excellent, the Spanish was pure, and scholars all over South America had noted that fact.

The final item on the program was the United States Pharmacopoeia, by W. C. Alpers. Mr. Alpers was not present, and the Chair stated that, without objection, the paper would simply be read by title and referred, and it was so ordered:

THE PHARMACOPOEIA OF THE UNITED STATES.

BY WILLIAM C. ALPERS.

The U. S. Pharmacopoeia, the book that we love and cherish more than any other worldly book, our true and faithful companion at our daily work, our guide through the difficulties and intricacies of our vocation, our pride as professional men, our most sacred treasure as pharmacists—how can I find words to describe and exalt this precious volume in a worthy way? To think of this book and its inexhaustible mine of knowledge and information arouses our enthusiasm, and fills us with emotion
and inspiration. For we see before us a work of such magnitude and beauty and—as far as possible—perfection, that no pharmacist whose heart has grasped the higher aims of our noble profession, can look upon it without that true inner satisfaction, that only faithful devotion to work and purpose can give. It is true, not every one will share this enthusiasm, and many will smile at what they think is mere exaggeration and uncalled-for idealism. There is the nagging critic to whom nothing is beautiful, grand nor sacred, and whose only enjoyment is the hunt for a small speck or stain to give him an excuse for spitting his venom on the whole work. There is the indolent and lazy whose mind is too sluggish to be aroused and elevated. There is the man of superficiality, who condemns first and examines afterwards, who is always in the negative and afterwards regrets his own doings. And there is the vast host of quiet pharmaceutical workers who suffer and moan under the weight of the adversities of our vocation and cannot find time and opportunity to uplift their eyes and take a more cheerful and encouraging view. All these do not share the enthusiasm that this glorious book inspires. To them it is nothing but a list of cold facts and statements, a mass of figures and formulæ, a dead volume for dead souls. Nor do they ever contribute to the revision or improvement of the Pharmacopoeia or of pharmacy in general; they plod along in their treadmill, unconscious of the possibilities and beauties of mental recreation.

Nor stands our profession alone in this respect. Take the botanist. The dry observer of facts sees in a flower or tree only so many petals and stamens, a leaf of such a shape, a seed of such a construction. The real botanist perceives the whole plant as one perfect, a beautiful work of nature; his mind rejoices at its harmony and symmetry, and his heart opens with enthusiasm in the thankful conception that he has recognised and displayed one of the mysterious secrets of creative power. So also to the thinking and devoted pharmacist our Pharmacopoeia is more than a list of facts. To him it is the history of his profession, the embodiment of pharmaceutical life, the plastic representation of everything that is worthy and noble in our existence. It has been said that pharmacy in the United States is fast running into pure commercialism, that there is nothing in it but drudgery, that professionalism and ethics are hollow words, that there are no higher aims and that a pharmaceutical ideal is an excrescence of sickly imagination. Glaucê at our book. Does that look like commercialism? Is not every page of it an appeal to professionalism? Is not every sentence a strong testimony of the brain work and depth of mind that has produced it? Nearly every formula, that has been brought down from former editions to the present one might elucidate the development and history of American pharmacy and might be used to demonstrate the progressive spirit of the profession. And this progressive spirit is the most notable instance of the difference between our Pharmacopoeia and
those of European countries. The latter, too, show the history of pharmacy of their respective countries in a marked way, and many preparations therein remind us of the mysticism of the Middle Ages and show how the light of truth and science gradually broke through the veils of ignorance and prejudice. But there is written on every page a stubborn conservatism that clings to old formulæ and old ideas and yields only when there is absolutely no other outlook. Not so our book. It is enlivened by the spirit of progressiveness, of energy, of fervent desire for truth; it does not look back and cling to old traditions and mysterious fogyes; its march is onward and upward.

In no country, therefore, does the Pharmacopœia represent in every detail the active life of the two professions, pharmacy and medicine. It is not, as some claim, the work of a few men; for even if the committee that finally decides on the various definitions and formulæ, consists only of ten or twelve men, these men do not, and cannot act according to their own desires or inclinations. To them is given a large amount of work, the result of the intelligent and thinking class of both professions. Whatever has been thought out and written and spoken of as a possible change or improvement of our Pharmacopœia during the last ten years is carefully collected. Abstracts are made from all journals of the world, from the proceedings of state and local associations, from the discourses and delineations of individuals. Where, in the whole world, for instance, is there such an office as that of the reporter on Progress of Pharmacy, who is the employee of our great Association? As we all know, it is his duty to collect whatever material is presented during these ten years, and his reports, therefore, represent the condensed accumulation of the progress in pharmacy and medicine.

It is a wonder that under these conditions our Pharmacopœia is largely superior as a progressive text-book to any similar book in the world. A new element will enter from now in its making, the element of the large commercial interests. Formerly they sat quietly by when the students of pharmacy evolved the Pharmacopœia; but since the standards laid down in this book have been legalized by the action of Congress, they recognize the necessity of also influencing the work from their standpoint. There are some who think that this new influence will work detrimentally and harmfully to the further development of our Pharmacopœia. I do not think so, and rather believe that a new, valuable factor will be added to its further improvement.

In the standardization the counsels of men who know the market of the whole world and know the important influence that such standardization will have on commercial interests, cannot but be useful and helpful. We cannot expect to prepare medicine from drugs that are far beyond the commercial possibilities. There the different elements that make up pharmacy in the broadest sense from the cultivator of the drug to the
final dispenser of the finished product must all act together and be in harmony.

Thus, let our Pharmacopoeia continue to be our pride and exalted guide: let us work together from one end of the country to the other in preserving and enlarging its beauty, its dignity, its usefulness, and let us take the highest and broadest view of its future. Sturdy work and high enthusiasm are required to accomplish this work. Let us not listen to the sneers of the skeptic who derides the ideal and laughs at enthusiasm. No great deed has ever been accomplished without the pioneer work of the idealist, which like the shining sun shows us our way. We never expect to call the sun our own and grasp its golden rays: but we follow its brilliancy, and its warmth gives us power and courage. So also will a high pharmaceutical ideal aid us to march forward, elevate our profession and make us strong in the adversities of the present, and hopeful for a glorious future. And the United States Pharmacopoeia is the embodiment of this progressive and active ideal.

This ended the symposium, and the program for the session.

The Chair stated that he wanted to extend his thanks to all those who had contributed papers, and all those who had had the patience to listen to them. It was now almost midnight, and a motion to adjourn would be in order.

Mr. Hallberg said that before adjourning, he wanted to move that a vote of thanks be tendered the Chairman for this delightful and edifying Symposium on the Pharmacopoeias of the World, and the motion was carried unanimously, by a vote put from the floor.

On motion of Mr. Wilbert, the Section then adjourned.

THIRD SESSION—SATURDAY MORNING, MAY 7, 1910.

The Section on Practical Pharmacy and Dispensing met pursuant to adjournment, at 10 o'clock, A. M., Chairman Otto Raubenheimer presiding.

The first paper on the program for the morning being one by Mr. Raubenheimer, he temporarily turned the Chair over to Mr. William R. White, Associate, while he read his paper on "Liniments."

U. S. P. AND N. F. LINIMENTS COMPARED WITH THOSE OF THE FOREIGN PHARMACOPEIAS.

BY OTTO RAUBENHEIMER, BROOKLYN, N. Y.

On investigation I find that the origin of liniments does not date as far back as it is generally supposed to. Such an excellent book as Traité de Pharmacie, by Eugène Soubeiran, chief pharmacist of the hospitals of Paris, published in 1839, only devotes one small page to these galenical preparations. In a price schedule, a copy of which I have in my library, the Herzoglich-Wirtembergische Medicinal-Ordnung, Stuttgart, 1786, not
a single liniment is quoted. In the present comparative review the writer must necessarily reiterate parts of his previous papers on "The Liniments of the U. S. P."; "The Liniments of the N. F."; "Linimentum Ammoniæ, Snow White and Permanent." Nevertheless this paper will contain some new matter which has not been stated before, as liniments are one of my specialties and I have always kept track of the literature regarding this important group of galenicals. In order to avoid repetition, I beg to state that I have compared the U. S. P. and N. F. liniments with those of the following Pharmacopœias:

Austria VIII, 1906;
France V, 1908;
Germany IV, 1900;
Germany Ergaenzungsbuch III, 1906;
Great Britain IV, 1898;
Japan III, 1905;
Netherlands IV, 1905;
Russia, V, 1902, reprint of 1906;
Switzerland IV, 1907.

LINIMENTUM AMMONIÆ U. S. P. VIII.

The formula for this popular liniment has been changed in every revision of our, as well as most of the foreign pharmacopœias. This again proves how puzzling such a simple preparation can be in the hands of different pharmacists. Every Pharmacopœia employs different oils, viz., the oils which are most popular in their own country. It is undoubtedly due to this fact that the U. S. P. made a change from olive oil to cotton-seed oil. And as this oil does not saponify very readily, a little oleic acid was added. To make the resulting liniment more fluid, a little alcohol was also added. But nevertheless this liniment thickens very much on keeping, and it is for this reason that the U. S. P. states: "This liniment should be freshly prepared when wanted." It is, however, impracticable to mix four ingredients together when 5 cents worth of "hartshorn liniment" is called for. As pointed out in my paper on "Linimentum Ammoniæ" all the latest pharmacopœias have adopted oil of sesame in the preparation of this liniment in the proportion of 3 to 4 parts of oil and 1 part of ammonia water. The Austrian Pharmacopœia which orders 20 parts ammonia water and 80 parts of sesame oil to be mixed by agitation in a bottle, describes this liniment as a white semi-fluid, of strong ammoniacal odor, which should not separate in two layers on standing. The Russian Pharmacopœia orders 3 parts of commercial olive oil (Provincialis); 1 part sesame oil and 1 part ammonia water, and states that this liniment must not separate into two layers, and that if it should thicken too much a few drops of alcohol should be added. The Japanese Pharmacopœia orders 1 part ammonia water and 4 parts sesame oil (the
same proportion as the Netherlands and the Austrian) with the directions to shake until a white homogeneous thick liquid is obtained. From experiments which I have conducted for years, I am prepared to make the statement that sesame oil is the proper oil to use in the preparation of ammonia liniment, because (1) it thus contains only two ingredients; (2) it can be prepared quickly and easily; (3) the resulting liniment is snow-white; (4) it is homogeneous and does not separate into two layers; (5) it has that proper creamy consistence, not too thick and not too thin: (6) it is permanent and will not thicken materially by age. Furthermore in my opinion it will be an advantage to order these ingredients which enter into this liniment by weight instead of by volume.

LINIMENTUM CALCIS U. S. P. VIII.

The French Codex orders equal parts by weight of olive oil and lime water; the British Pharmacopoeia orders equal volumes of the same ingredients; the Japanese Pharmacopoeia orders equal parts by weight of sesame oil and lime water; the Elenchus to the Austrian Pharmacopoeia, the Swiss Pharmacopoeia and the Ergenungsbuch (supplement to the German Pharmacopoeia) all order equal parts by weight of linseed oil and lime water. The last two authorities order this liniment to be freshly prepared when called for. When I questioned the necessity of this requirement in my correspondence with a German pharmaceutical authority I was informed that this was evidently done because the lime in the lime water employed would in time be changed to calcium carbonate. I cannot agree to this, because calcium hydroxide in saponifying linseed oil is changed to calcium linoleate. Furthermore, I find that this liniment actually improves by age, and last but not least, whenever carron oil is required for burns and scalds it is wanted in a great hurry. I would respectfully suggest to the Revision Committee that the ingredients in this liniment should be weighed instead of measured, being simpler and cleaner.

LINIMENTUM CAMPHORAE VIII.

In my paper on the liniments of the U. S. P. I went into all the details, which it is not necessary to repeat. In all of the foreign Pharmacopoeias this liniment is official under the title of "oleum camphoratum." As this preparation is generally called for by the public and mostly prescribed by the physicians under the title camphorated oil, this name most certainly should be given as a synonym in the next revision. I also want to call your attention that a number of cases of prosecution for adulterated camphorated oil have been thrown out of court because the U. S. P. did not contain this title or synonym. A great many of the pharmacopoeias use sesame oil in the preparation of this liniment, which in my opinion is in the first place less gummy and sticky than cottonseed oil, and in the second place, a better solvent for camphor, so that it dissolves readily without
the application of heat. I also beg to call to your attention that the employment of heat in the present directions of the U. S. P. has been the direct cause for court decisions that this preparation cannot contain 20 per cent. camphor. The U. S. P. should, besides a short physical description, including specific gravity, also give an assay for determining the strength of camphor liniment. The Austrian Pharmacopoeia, which orders 1 part of camphor and 3 parts of sesame oil, gives the following approximate method of determining the strength of oleum camphoratum: "When 10 Cc. of oleum camphoratum and 10 Cc. alcohol (90 per cent.) are well shaken together in a graduated tube, then the separated alcoholic layer should not measure less than 13 Cc." While this is not an exact assay, it will certainly serve as an approximate test which can be readily applied by the average pharmacist. Experiments in the application of this test to the U. S. P. camphor liniment are going on in my laboratory and will be published in due time.

LINIMENTUM CHLOROFORMI U. S. P. VIII.

This liniment is superior to the preparations of the foreign pharmacopoeias which are mixtures of chloroform and some fatty oil. Our U. S. P. should give no method of determining the percentage of chloroform. The latter can readily be shaken out by centrifugal force.

LINIMENTUM OPII COMPOSITUM N. F. III.

In addition to my remarks in my former paper, I want to state the following: In tracing the origin of this liniment I came across a formula for Linimentum Canadense in the Manual of the N. Y. Pharmaceutical Society published in 1858, a copy of which I have here for your inspection. (This Manual can justly be called the forerunner of our National Formulary.)

Olei Menthae piperitae partem unam. 
Tincturae Opii partes duos. 
Olei Terebinthinae. 
Alcohol Vini. 
Liquoris Ammoniaci caustici ana partes octo. 
Misce.

LINIMENTUM SAPONIS U. S. P. VIII.

I beg to call your attention to a cold-process Spanish olive oil soap which when grated will readily and completely dissolve in a mixture of alcohol and water, without the application of heat.

LINIMENTUM SAPONATO-CAMPHORATUM N. F. III.

This preparation is official in almost every pharmacopoeia, its formula however differing very largely. The present N. F. formula which orders "White Castile" soap does not produce a satisfactory solid opodeldoc. Furthermore the stronger ammonia water in the N. F. formula should in my opinion be changed to ammonia water (10 per cent.) which is the in-
ingredient in the foreign pharmacopœial formulas. Very likely the Latin term Liquor Ammonii Caustici, which, however, is of 10 per cent. strength, was translated into Caustic Ammonia water of 28 per cent. The Dunning formula using stearic acid and sodium carbonate produces a very satisfactory opodeldoc. The Austrian Pharmacopœia also uses these ingredients with the addition of glycerin and the Swiss Pharmacopœia saponifies lard with the solution of sodium hydroxide, whilst the German Pharmacopœia employs "Sapo Medicatus" prepared by the saponification of equal parts of lard and olive oil with sodium hydroxide.

LINIMENTUM TEREBINTHINÆ ACETICUM N. F. III.

As pointed out in my paper on the liniments of the N. F., the thickening of this liniment can be readily prevented by using the yolk of 2 eggs and the albumen of one in place of the entire two eggs as required for twice the quantity of the present N. F. formula. The Swiss Pharmacopœia and also the supplement to the German Pharmacopœia direct to prepare this liniment by emulsifying 5 parts of olive oil with 15 parts of yolk of egg and the necessary water and then adding the oil of turpentine and acetic acid. The Ergaenzungsbuch calls this liniment "Stokes" which should, however, be Stokes as it was originated by Dr. William Stokes, of Dublin, the originator of Stokes Expectorant, who also brought the Withering treatment for dropsy, with digitalis, before the Medical Society of Edinburgh, and whose name is indelibly associated with medicine in the connection with the peculiar breathing known as the Cheyne-Stokes respiration.

Dr. Stokes and his expectorant.—G. B., New York.—Dr. William Stokes was born at Dublin, Ireland, in 1804. He was the son of a physician, Dr. Whitley Stokes, at that time a professor of medicine in the University of Dublin. William Stokes obtained his degree from the University of Edinburgh in 1825, and from the University of Dublin in 1839. For a time he was physician to Meath Hospital, associated with Dr. Robert J. Graves. He was the editor of the Dublin Journal of Medical Science, founded the Pathological Society in 1838, was physician to Queen Victoria in Ireland in 1861, a fellow of the Royal Society, and at one time president of the Royal Irish Academy. He succeeded his father as regius professor of physic at the University of Dublin.

Dr. Stokes was the author of a number of works upon the diseases of the chest and heart, both alone and in conjunction with Dr. Graves. In a footnote to one edition of his Treatise on Diagnosis and Treatment of Diseases of the Chest, edited by Hudson and published in 1882, is given the following formula for an expectorant:

Decoction of polygala senega .................. 5 ounces.
Syrup of tolu ................................... 1/2 ounce.
Tincture of opium, camphorated ................ 2 drams.
Tincture of squill ................................ 2 drams.
Ammonium carbonate ............................ 15 or 20 grains.
In this same work also is given a formula for a liniment to be used as an application in the treatment of bronchitis: this is nearly identical with the formula for Stokes' liniment in the National Formulary, the amount of acetic acid being less in the original recipe and only the yolk of the egg being used.

In reply to the query, "How does his formula [for expectorant] happen to be in the National Formulary?" we would say that presumably it was adopted and changed by the National Formulary committee because that committee thought it worthy.

Besides the preparations mentioned there are several others in the N. F. which properly belong to the liniments, namely:

Tinctura Saponis Viridis Compositum N. F. III.

In as much as the title "\textit{sapo viridis}" of the U. S. P. 1880 has been rightly changed to \textit{sapo mollis} in the U. S. P. in 1890, and inasmuch as the title Tinctura \textit{Saponis Viridis} of the U. S. P. 1880 has also been rightly changed to Linimentum \textit{Saponis Mollis} in the U. S. P. 1890 therefore that old title Tinctura \textit{Saponis Viridis Compositum} of N. F. I, II, III, should most certainly be changed in the next edition of our N. F. to the proper title corresponding to the Pharmacopoeial title, viz., Linimentum \textit{Saponis Mollis Compositum}.

Petrolatum \textit{Saponatum Liquidum}.

I beg to call your attention to the many formulas in the Supplement to the German Pharmacopoeia for medicated vasolinenta and quite especially to \textit{Vasolimentum Iodatum} containing 10 per cent. iodine; together with an excellent assay process.

Before closing I must not forget another class of liniments which, by the way, are one of my hobbies, namely:

\textbf{OLEA INFUSA N. F. III.}

And quite especially to \textit{Oleum hyoscyami infusum} or as called by some of the foreign pharmacopoeias \textit{coctum}.

The process employed in the N. F. as well as the foreign pharmacopoeias is the Eugen Dieterich method consisting of macerating the ground herb with ammoniated alcohol in order to liberate the alkaloids and then infusing with the oil. Olive oil was formerly used; but sesame oil has replaced it in the latter Pharmacopoeias and sesame oil should most certainly displace the mixture of lard oil and cottonseed oil in the N. F. Again I beg to point out my comments in the N. F. Committee (Bulletin A. Ph. A., Dec., 1909, page 483) that the Swiss Pharmacopoeia orders this oil to be prepared in a copper vessel and describes it as clear and dark-green. In place of a copper vessel any ordinary dish will answer, if a few copper coins are added when the oil is infused. You will please notice the beautiful rich dark-green color of the submitted sample prepared according to the Swiss Pharmacopoeia; and, although color is said to be no criterion, I
am convinced that the physician as well as patient and customer would prefer such a preparation to one of brownish-green or greenish-brown color. The objection that this oil might contain copper has been nullified by the chemical examination of the oil by Prof. La Wall.

**OLEUM HYOSCYAMI COMPOSITUM N. F. III.**

The formula of the French Codex is a rather complex one, although not quite as complicated as the original formula for Balsamum Tranquillum quoted in Soubeiran's Traité de Pharmacie, which was an infused oil of six fresh and twelve dried drugs. The Swiss Pharmacopoeia directs to prepare this oil by the addition of one Gm. each of oil of lavender flowers, peppermint, rosemary and thyme, to 1000 Gm. of oil hyoscyami. The sample herewith submitted, which contains 10 drops of each of these oils in 100 Gm., I consider an improvement because it has more of an aromatic odor. The formula of N. F. III calls for 2 drops of each oil of absinth, lavender flowers, rosemary, sage and thyme to 100 Cc. of infused oil of hyoscyamus. By increasing the amount of essential oil from 2 to 10 drops, the aromatic odor can be greatly improved. The main benefit with this or a similar formula will be that the preparation can be made extemporaneously.

**CONCLUSION AND SUGGESTIONS.**

In conclusion I beg to state that taking it all in all, the formulas for the liniments of the U. S. P. and N. F. give very good satisfaction, and are the equal if not the superior of those or the foreign Pharmacopoeias. It is our duty to follow our standard books, of which we can be justly proud, and which now actually have been made law books, and it is furthermore our duty to suggest improvements, if possible, to the revision committees of the U. S. P. and N. F.

**The Acting Chairman:** We have listened to this most excellent paper by Mr. Raubenheimer. Is there any discussion?

**Mr. Hynson:** I would like to ask Mr. Raubenheimer if he does not think it is well to use definite products instead of soap. I think if that can be done it should be, on all occasions. And I take occasion again, like I did in connection with what was said by my friend Beringer, for whom I have the profoundest respect for his ability, to call attention to the fact that Mr. Raubenheimer advises the use of copper coin in coloring these oils. That seems so foreign to the usual way he does such things that I cannot understand it.

**Mr. Raubenheimer:** Instead of using an indefinite substance use a definite compound, and follow the foreign Pharmacopoeias. I have done so for years. Some soap is hard; some is soft—like Castile soap, which differs very much; so it is much better to use a definite article. Of course I do not suppose we will ever agree on copper coins. I think it is a very good thing, and if you make any infused oil like that, you have them brand new. That is the point, and the big point of it is that no one can find any copper in it. Copper is certainly a big advantage.
Mr. Hynson: Mr. Chairman, by sufferance I allowed you to read your paper, when I had the right of this floor, by action of this body. You will remember that you entertained a motion, and it was carried, that the report of the Committee on the Chairman's Address should take precedence at this session; and I now claim the right that was given us to bring before the Section the report of the Committee on the Chairman's Address.

The Chairman: Certainly you can have it, Professor Hynson; but when we opened our meeting there were but a few of our members here, and I thought I would read my paper, as I am apt to be called away at any minute.

Mr. Hynson: I allowed you to read your paper first because I wanted to draw a crowd when the report was read.

The report of the Committee on Chairman's Address was then read.

REPORT OF COMMITTEE ON CHAIRMAN'S ADDRESS.

Your Committee on the Chairman's Address calls the especial attention of the entire membership of the Association to this most interesting paper and to the careful and able discussion of many of the problems confronting Pharmacy today: We believe that it is because the carefully thought out suggestions of such devotees to Pharmacy as your chairman are not sufficiently studied that better progress in pharmaceutical reforms have not been made: we believe that it is the non-discovery and non-adherence to truth that prevents the more ready attainment of our ideals; such truths as are so forcibly promulgated by Chairman Raubenheimer.

We believe with the chairman that the progress of pharmacy is greatly retarded by the duplicating of the same compound as specialties; the improper and incomplete labeling of new chemicals; the similarity of names or titles; the suggestions of manufacturers in their price lists and on other labels of the possibility of making galenicals by other than pharmacopoeial methods;—by the dilution of fluidextracts, which strangely enough is inconsistently endorsed by the several such formulas appearing in the U. S. P. and N. F.

We believe the latter hindrance needs the attention of the Association, manufacturing pharmacist and especially government and state officials who have to do with the enactment and enforcement of food and drugs laws—we believe the publication of such formulas pernicious and should be restricted.

We endorse and heartily present to the practising pharmacists of the Association the ten specific recommendations made by the Chairman: we also endorse the recommendations to the Association as being worthy of serious consideration by the Council and therefore respectfully call the attention of that body to the subjects as presented by the Chairman.

The unique suggestion of Dr. Bastedo regarding the certification of pharmacists to which the Chairman calls attention should not be allowed to pass and the suggestion is made that a special committee of this Section be formed to consider the subject, and report at the next annual meeting.

The Committee wishes to lend the Chairman all the encouragement his unselfish devotion to pharmacy and his abilities deserve.

Respectfully submitted,

Henry P. Hynson,
George M. Beringer.

Acting Chairman: You have listened to the report of the Committee on Chairman's Address. Is there any discussion of this report? If not, a motion will be entertained for its adoption.
Mr. Ladish: I make a motion that the report be adopted, and that the recommendations be concurred in.

Motion seconded and carried.

Mr. Raubenheimer: I move that the Committee be discharged, with thanks.

Motion seconded and carried.

Mr. Raubenheimer: I am very thankful to the Committee. I was already getting a little nervous. Professor Hynson said he was going to begin to worry me, and there were some things in that address that I was a little worried about.

Mr. White: There was one thing that I noticed the Committee did not cover, and that was the Recipe Book. I did not notice any reference to that; it was the recommendation of the report of the Chairman that the Recipe Book be printed by the Association.

Mr. Hynson: Well, that was one of the recommendations that we endorsed, that it be referred to the Council, for consideration. We thought that the best way to dispose of it.

The Chairman: The next in order is the report of the Nominating Committee. They are holding a session now, and I understand will be ready to report very soon. In the meantime we had better have a short paper read. Mr. Hynson, suppose you read your paper now.

Mr. Hynson: This paper, according to the regular rule, should not be read, but it is one of great interest, I think, and if there is no other paper ready, I will read it. You know this is a paper written by some one else.

EFFERVESCENCE.*

BY W. J. LOWRY, JR., BALTIMORE.

Effervescence is defined in the dictionary as: "Irrepressible excitement or emotion" and this definition may explain the immense popularity of a well-known proprietary effervescent preparation for the relief of the invariable headache in "the cold gray dawn of the morning after" an evening of irrepressible excitement or emotion on the homeopathic theory of: "Similia similibus curantur."

Whether this theory holds good or not, it can not be gainsaid that effervescence, as applied to cold liquids in a state of "irrepressible excitement or emotion" and intended as beverages, increases not only their palatability, but the bubbles of carbon dioxide have a tendency to act as letters of introduction to the stomach and cause the liquid to be a much more welcome guest than it might otherwise be.

If a pleasant beverage is made more pleasant by effervescence, then it is reasonable to presume that otherwise unpleasant medicine may be made pleasant or, at least, acceptable by these same bubbling "letters." This, then, being so, the administration of medicaments in effervescent form is

* Being the Chairman's report of a special committee, to which the Effervescent Salts of the National Formulary were referred, by "Sub-Committee V" and composed of Joel J. Barnett, W. A. Whittle and the author.
not only desirable but, in some cases, is the best way in which some remedies may be given.

The U. S. P. Effervescing Solution of Magnesium Citrate is an excellent illustration of this class of liquids and needs no comment. In addition to this, there are the N. F. solutions of magnesium sulphate, potassium citrate and sodium citro-tartrate.

These solutions can be easily prepared by the pharmacist, but granular powders which, when dissolved in water, cause effervescence, seem too great a task for the average apothecary to accomplish.

The use of this class of pharmaceuticals has increased to an enormous extent and every pharmacist should be in a position to prepare, not only U. S. P. and N. F. granular effervescent powders, but, also, any for which he has call or for which he can create demand.

As is well known, the effervescent powders are composed of the medicinal ingredient and alkaline bicarbonate (usually sodium bicarbonate) and either tartaric acid, citric acid, or both; the dry, fine powders being simply mixtures of the medicinal agent, sodium bicarbonate and tartaric acid. The granular powders, generally known as granular effervescent salts (and in this paper hereafter called G. E. salts) are a fused and dried mixture of the medicament, sodium bicarbonate and citric acid, or, the medicament, sodium bicarbonate, citric and tartaric acids. This is generally the case, but they are still prepared, in some cases, by moistening a mixture of tartaric acid, sodium bicarbonate and the medicament, with alcohol, and drying. Sugar is very often added. In some cases, to sweeten and in others to cheapen, but such salts are prone to change unless used in a short time.

The U. S. P. salts are an excellent line, with the exception that their citric acid content is too low to form good granules, while the N. F. G. E. salts are worthless and the working formulas are all wrong.

The idea of forming a neutral salt when saccharated citric or saccharated tartaric acid is mixed with an equal weight of saccharated sodium bicarbonate and dissolved, is a good one and if the quantity of citric acid be sufficient to form good, stable granules, their principle would be ideal; but, unfortunately, although they look very well on paper and the general process, as laid out in the N. F., would indicate plain sailing, they do not produce the results expected in practice.

One serious objection to the saccharates is the sugar; this never occurs in the natural mineral waters, for which the corresponding salts should furnish portable as well as potable substitutes, which the sweet solutions do not do. In the heating necessary to form the granules, the sugar is generally darkened; either immediately, as shown by the slight tinge of yellow, if great care be not exercised, or on standing for any length of time, even if no signs of discoloration appear when the salt is taken from the heat.
Sugar also dilutes the quantities of acid and alkali to such an extent that if the proportion of medicament is high, it is almost impossible to get a granule, and the resulting mixture has very little, if any, effervescing properties.

At least half the finished product should be effervescing base, in order to get a lively solution, though less may be used, on special occasions, but always at a sacrifice of rapid solution and of the amount of gas liberated.

The N. F. basis for dose is 90 grains, while 60 grains seem to be the popular quantity, so it is suggested that a dose of 60 grains be made the basis on which the medicinal ingredients be calculated and a smaller quantity of sodium tartrate and citrate will be given each time; for it seems there are cases in which too much of the alkaline citrates and tartrates are undesirable.

A serious objection to making the U. S. P. G. E. salts in any quantity at all is the order of mixing the ingredients. The citric acid should always be added last, on account of its hygroscopic nature, for if there be considerable humidity the powder will lump-up and cake and, when fused, will be full of very wet spots, the resulting granules being a mixture of very wet ones, with considerable fine powder.

Another decided objection is the stirring-up of the fusing powder; this should not be disturbed. The melting salt should not be touched until it has entirely fused. If, after about four minutes, it seems all right, feel it by gathering a small lump in the hand. If it is of the proper consistency, take it out and hustle it through a sieve in a hurry; if it is not just right, the door should be promptly closed; it should not be kept open a second longer than necessary. Feel every two or three minutes until it is just right.

It is not best to make G. E. salts that are to be kept for any length of time, when the humidity is much beyond normal, as even short exposure to the air, after taking from the oven and while filling the container, may be enough to cause the salt to become damp. If the medicinal ingredient contains water of crystallization, use the proper amount of the anhydrous equivalent and if this be large, it may be necessary to increase the quantity of citric acid, always neutralizing the increase with sodium bicarbonate, decreasing the tartaric acid. For all practical purposes one part of citric acid requires one and one-fifth parts of sodium bicarbonate (1 to 1.2).

**GENERAL DIRECTIONS FOR GRANULAR EFFERVESCENT SALTS.**

Conditions of powders: These should all be of number 60 degree of fineness. Pass the sodium bicarbonate through a No. 24 or 30 sieve, then the medicament; the tartaric acid is next passed through and these powders mixed; lastly pass the citric acid through and then mix the whole batch thoroughly.
FOR GRANULATING IN AN OVEN.

Spread the powder evenly, about 3/8 inch thick, on a sheet of paper, on a canvas tray, a glass plate or a shallow porcelain or enameled-ware dish. Then place in an oven heated to not less than 95° C. and not over 105° C., and allow it to remain there, but without stirring, until of the consistency of fresh bread, not quite pasty, but too moist to be dry and too dry to be moist (this is the critical period). Immediately transfer to a No. 5 or 6 sieve and force through (on the few hard granules that usually are formed; you may have to use a pestle). Spread out the granules on the tray and dry in the oven at a temperature not exceeding 50° C. The length of time required for the drying-out depends on the atmospheric conditions and may take from three to six hours. When dry, pass through a No. 6 or 8 sieve and transfer to air-tight containers and keep securely closed, in a dry place.

TO GRANULATE ON A WATER-BATH.

The N. F. plan of placing the mixed powders in a water-bath and stirring till dry, is a very quick method for small quantities, at the dispensing counter and where small (say No. 10) granules are suitable; it is an excellent way of proceeding. In these experiments, close to one hundred different 100 Gm. lots of salts were made by the N. F. process, but with the readjusted formulas. These granulations required about ten minutes, from the time of placing the powder in the briskly boiling water-bath (an ordinary agate-ware, double oatmeal boiler was used) to produce perfectly dry granules, which were passed through a No. 8 sieve and immediately bottled.

Some of these salts, made seven months ago, are "as good as new" today and not a lot that was experimentally successful, has gone bad.

With experience had in making thousands of pounds of G. E. salts and the experience gained in making salts on a very small scale, in preparing this paper, it is recommended that the oven method be used for all large quantities and the water-bath method be used for small quantities, say from 100 to 250 Gm.

As the result of numbers of experiments with an effervescing base for G. E. salts, made according to the oven method, it was found that the amount of citric acid necessary to form good granules should be about 25 per cent. of the calculated yield. If one pound is to be made, 4 ounces of citric acid will be required and as there is a loss of both water and carbon dioxide, it will be necessary to use more than one pound of powder, in order to yield the pound. Experience has taught that from 110 to 120 parts of powder will yield 100 parts of finished product and, in these formulas, 115 and 120 parts are calculated to yield 100 parts.

As an effervescing base, the following is suggested, for oven granulation:
Citric acid ........................................... 26.0 parts.
Sodium bicarbonate ................................. 30.0 "
Tartaric acid, 0.47 × 60= ........................ 28.2 "
Sodium bicarbonate, 0.53 × 60= .................. 31.8 "
Weight before fusing ............................... 115.0 "
Loss of water and carbon dioxide .................. 15.0 "
Yield after fusing and drying ...................... 100.0 "

In order to simplify the calculations, 100 parts are made and, in order to make this quantity, 25 parts of citric acid must be used to form the granules. To practically neutralize this will require 30 parts of sodium bicarbonate. These 25 parts + the 30 parts, give 55 parts, that are absolutely necessary. There is then required the difference between 115 and 55 parts, or 60 parts of a mixture of tartaric acid and sodium bicarbonate, each part of which contains 0.53 parts of sodium bicarbonate and 0.47 parts of tartaric acid, therefore, 60 × 0.53 = 31.8 parts of sodium bicarbonate and 60 × 0.47 = 28.2 parts of tartaric acid.

The appearance of sodium bicarbonate twice in the formula may seem peculiar, but when a salt containing a medicament is to be made, this will be explained. For example: Wanted, 1 pound of a G. E. salt containing 5 grains of potassium bromide to each 60 grains, to be granulated in an oven.

Citric acid, 25 × 70 parts (1 lb. = 7000 grs. - 7000 ÷ 100 = 70) ........................................... 1750 grs.
Sodium bicarbonate, 30 × 70 parts (1 lb. = 7000 grs. - 7000 ÷ 100 = 70) ..................................... 2100 grs.
Potassium bromide ..................................... 583 grs.

1750 + 2100 + 583 = 4433 grains of the three ingredients above, subtracted from 115 × 70 = 8050, the calculated yield, equals 3617 grains of the tartaric acid and sodium bicarbonate mixture.

Tartaric acid, 47 × 3617= ................................... 1700 grs.
Sodium bicarbonate, 53 × 3617 = ............................ 1917 grs.
Total weight of powder in formula 115 × 70 = ................... 8050 grs.
Loss of carbon dioxide and water 15 × 70 = .......................... 1050 grs.
Yield 1 pound or ........................................... 7000 grs.

As an effervescing base for small quantities to be made in a water-bath and finished up before removing from the heat; particularly for use at the dispensing counter, the following is proposed:

Citric acid ........................................... 16.5 parts
Sodium bicarbonate ................................. 20.0 parts
Tartaric acid, 47 × 83.5 = .......................... 39.25 parts
Sodium bicarbonate, 53 × 83.5= ...................... 44.25 parts
Weight before fusing ............................... 120.00 parts
Loss of carbon dioxide and water .................. 20.00 parts
Yield after fusing and drying ...................... 100.00 parts
In order to simplify the calculations, 100 parts are used and in order to make this quantity, 16.5 parts of citric acid must be used to form the granules; to practically neutralize this will require 20 parts of sodium bicarbonate. These 16.5 parts plus the 20 parts, give 36.5 parts that are absolutely necessary. There is then required the difference between 120 and 36.5 or 83.5 parts of a mixture of tartaric acid and sodium bicarbonate—each part of which contains 0.53 part of sodium bicarbonate and 0.47 part of tartaric acid, therefore, 83.5 x .53 = 44.25 parts of sodium bicarbonate and 83.5 x .47 = 39.25 parts of tartaric acid.

An example of a G. E. salt made according to the above, follows:

Wanted: 4 ounces G. E. salt, containing 1 grain of caffeine, citrated, and 10 grains of sodium bromide in each 60 grains. Consider 4 ounces 1800 grains in order to simplify matters.

Citric acid, 16.5 x 18 parts = (1800 ÷ 100 = 18) = 297 grs.
Sodium bicarbonate, 20.0 x 18 parts = (1800 ÷ 100 = 18) = 360 grs.
Caffeine, citrated .......................................................... 30 grs.
Sodium bromide ............................................................. 300 grs.
Tartaric acid, 0.47 x 1173 = ....................................... 552 grs.
Sodium bicarbonate 0.53 x 1173 = .......................... 622 grs.

(297 + 360 + 30 + 300 = 987. 2160–987 = 1173).
Powder before fusing 120 x 18 = .......................... 2160 grs.
Loss of carbon dioxide and water 20 x 18 = .............. 360 grs.

Yield practically 4 ounces or .................................. 1800 grs.
1800 + 60 = 30–60 grain doses...30 x 1 = 30 grs. caffeine citrated.
1800 + 60 = 30–60 grain doses...30 x 10 = 300 grs. sodium bromide.

With these two bases, it is possible to make a full line of G. E. salts and below will be found formulas for most of the N. F. salts and for a few others which have come into popular use.

As effervescent citrate of iron and quinine and effervescent phosphate of iron are so rarely called for and are so very difficult to make and to handle, it is suggested that they be dropped.

A final caution.—Be sure that the citric acid used has been recently powdered from perfect crystals which have not effloresced; never use any other kind.
Mr. Hynson: As I have said, that paper was not mine; but I believe these young men are members of the Association, and have done a great deal of work on this subject. I think it would be well if the special attention of the National Formulary Committee were called to it.

The Chairman: I will entertain a motion that the paper be accepted and take the usual course; and also be referred to the National Formulary Committee. If there is no objection, it will be so ordered.

The next paper is on "Syrups" by Mr. Beringer.

Mr. Beringer: I have not a very elaborate paper on this subject, but I think there are a few points that ought to be brought out.

THE SYRUPS OF THE UNITED STATES PHARMACOPEIA COMPARED WITH THOSE OF SOME OF THE IMPORTANT FOREIGN PHARMACOPEIAS.

BY GEO. M. BERINGER.

A comparative study of the methods adopted by the various pharmacopoeias is always of value as not only indicating the practice in those countries but also how some of the problems that are common to all are handled and in this we may find ideas that are well worthy of adoption in our own. For the present study of the official syrups the following pharmacopoeias have been compared with the U. S. P. and the syrups as a class tabulated: The British 1898, the German 1900, the French 1908, the Swiss or Helvetica 1907, the Austrian 1906, the Danish 1907, the Swedish 1901, the Italian 1909 and the Spanish 1905.

The number of substances exhibited in the form of syrup varies greatly in these works and possibly indicates the prevailing preference of certain nationalities for sweet things. The French leads with 51 titles devoted to the class; the Spanish comes next with 50 and the Swiss has 31; the United States has 29; the Italian 24; the British and Austrian each 22; the German 18; the Swedish 16; and the Danish only 10.

The variety of medications exhibited in this form in the new French Codex is remarkable as it embraces not only the usual complement of saccharine solutions of chemical medicaments but also a number of drugs of vegetable origin that are not commonly exhibited in this form such as aconite and valerian.

The comparison shows that there are very few syrups indeed that are common to all of these pharmacopoeias as only three such can be named, namely, simple syrup, syrup of orange peel and syrup iodide of iron. A few are common to a majority, some to several and quite a number are peculiar to the one country only. Among such we may illustrate the U. S. P. compound syrup of squill, and the aromatic syrup of rhubarb is likewise not mentioned in the other works. Many of the syrups that are popular in this country and which we might very properly suppose were universally used appear to be scarcely known abroad. Syrup of tolu does
not appear in either the German or Austrian Pharmacopoeia and even syrup of ipecac is omitted from both the British and Danish and syrup of wild cherry is only recognized in the U.S.P. and British and the same is true of syrup of squill, and it is surprising to note that the British does not recognize syrup of ipecacuanha. The recognition of certain formulas by a limited number of pharmacopoeias may indicate the territorial use; thus syrup of peppermint is in the German, Swiss and Austrian, leading to a belief that its use is largely in central Europe; and the same is shown in syrup of maidenhair fern official in the French and Swiss.

The popular use of syrups as a vehicle or adjuvant is shown in all of these pharmacopoeias by what are really only flavored saccharine solutions. In the U.S.P. we have for this purpose citric acid, almond, orange, orange-flower, rose, tolu and ginger syrups, but the other aromatic syrups and especially the fruit syrups like cherry, raspberry, red currant, mulberry, and quince are neglected although a number of these are certainly worthy of attention and use. The National Formulary has attempted to supply formulas for only very few of these. In these flavoring syrups one can detect certain peculiar national likings; for example, aromatic syrup in the British and the syrup of fresh blue violet petals, and the syrup of the dried violets in the Spanish.

The nomenclature and arrangement of the formulas of the U.S.P. must be approved as superior to most of these foreign works. The method adopted in the French and Spanish Pharmacopoeias of arranging the formulas under the vernacular names and giving the Latin titles as sub-titles does not appeal to us. The nomenclature of the U.S.P. has been criticized in some quarters, but on examination of our official titles we are convinced that we are as near correct and in the main as uniform and harmonious in style of title as are most of the foreign. There is not that uniformity and harmony among the foreign that the critics of the U.S.P. would lead us to infer. It is quite possible that when the lexicographers of all the nations will agree as to the gender and declensions of the numerous nouns used as drug names that we will then have a basis for universal titles and the lack of harmony in this respect may be then removed from the pharmacopoeias. Recently it was suggested that the U.S.P. should change the Latin title "Syrupus" to "Sirupus" and it was argued that the latter was the title of most of the continental pharmacopoeias. As a matter of fact the German, Swiss and Italian use "Sirupus" and the British, French, Austrian, Danish, Swedish and Spanish agree with the U.S.P. in using "Syrupus." As to harmony of titles a few examples will show how this is non-existent: The Ph. Gr. uses Sirupus Amygdalarum, the Ph. Aus. Syrupus Amygdalinus and the Ph. Fr. Syrupus Amydalæ, the Ph. Hl. has Sirupus Mannae Compositus, the Ph. As. Syrupus Sennae Compositus, the Ph. It. has Sirupus Sennæ et Mannæ, and the Ph. Dn., and the Ph. Sv. each use Syrupus Sennæ Mannatus for their modifications.
of the same formula; for syrup of red currant the Ph. Fr. has Syrupus Ribis Fructus, the Ph. As. Syrupus Ribium, and the Ph. Hs. Syrupus Grossulariae and one has only to examine the latinized titles for such words as "phosphate," "hypophosphite," and "iodide" to be convinced that international harmony in official titles is as yet a myth.

The European method of weighing liquids as well as solids and the finished product is recognized in the U. S. P. only in the syrup iodide of iron. It is notable, however, that this idea has received such extended use in many of the British formulas for syrups. As a principle leading to accuracy of dosage this has a very serious defect. If through carelessness on the part of the operator there is a variation in the density of the syrup or any of the other ingredients, then there will be a variation in the volume and a corresponding variation in the calculated dose; again it must be based upon the presumption that the prescriber has continuously well in mind the percentage strengths and gravities of the liquids directed. As this is, of course, far from the fact there must be introduced in each prescription an element of uncertain dosage.

USE OF DISTILLED WATER.

It is to be noted that some of the foreign pharmacopoeias as well as the United States are not careful to direct distilled water in the making of syrups, and the U. S. P. is deficient in several instances where this is an important item. Notably in the syrup of hydriodic acid where water is directed instead of distilled water, which in this syrup is particularly important. The Danish Pharmacopoeia is a model in this respect.

THERAPEUTIC TITLES.

The N. F. especially has been criticized for the use of titles that might be construed as indicating therapeutic value. The foreign pharmacopoeias are far from free of this same criticism. For instance, the French has as a title, Syrupus Anthelminticus and Syrupus Diureticus Compositus, and both the French and Austrian, Syrupus Pectoralis.

PREPARATION FOR DRUG.

While the U. S. P. has now generally adopted the principle of making syrups like rhubarb and senega and ipecac from the fluidextracts, it is characteristic of the most foreign pharmacopoeias that they direct such preparations to be made direct from the drug and this principle to compel the pharmacist to prepare his own official formulas throughout is noted in all of these pharmacopoeias.

USE OF GLYCERIN IN SYRUPS.

The writer has elsewhere called attention to the advantage secured in extracting and permanency of some of the syrups by addition of some glycerin. It is noted that this idea is being introduced in some of the
foreign pharmacopoeias, especially in the Pharmacopoeia Helvetica where it is used in several of the official formulas.

SYRUPUS.

The official syrup is called Syrupus Sacchari in the Ph. Dan. and Ph. Sv. "Simplex" in the Ph. Gr., Ph. Fr., Ph. Hl., Ph. Aus., and Ph. His. The formula is practically the same in all with the stated sp. gr. varying from 1.30 to 1.35. It is to be noted that in some of these foreign authorities distilled water is not directed. The U. S. P. should include, however, tests for glucose or inverted sugar.

SYRUPUS AMYGDALÆ.

In several of the foreign pharmacopoeias this syrup is an emulsion of either sweet almond or the sweet and bitter almond mixed. The U. S. P. VIII has made a radical change in this formula although that had previously also used the emulsion formula. In the last revision the syrup of almond was changed to merely syrup flavored with orange-flower water and a small quantity of spirit of bitter almond. The quantity of almond is too small and the flavor soon undergoes change. It in no wise resembles the foreign formulas, and as this is more frequently prescribed by foreign physicians or used in filling prescriptions written abroad, it is apparent that the marked difference in character is apt to cause comment with customers. It is believed that the pharmacopoeia should return to formula of the U. S. P. 1890.

SYRUPUS FERII IODIDI.

In this preparation the U. S. P. has conformed to the international formula recommended by the Brussels Conference, and most of the foreign pharmacopoeias have followed the same, but it is notable that the French Pharmacopoeia, recently issued, still retains a syrup iodide of iron, as syrupus ferri iodidi gallicus containing only .5 per cent. of ferrous iodide, and then publishes in the appendix the entire articles of the Brussels protocol. The Ph. Br., however, has not been revised since this international conference, and this still retains the 10 per-cent. ferrous iodide syrup. The U. S. P. uses hypophosphorous acid as a preservative in this preparation, but it likewise should direct that it be added only after the solution has become cool, as added when hot decomposition will ensue. It is noteworthy that the Ph. Hl. and Ph. Aus. each directs citric acid for this purpose and the French Codex tartaric acid; the others omit preservatives.

SYRUPUS IPECACUANHÆ.

The formula of the Brussels Conference is adopted only in the Ph. Hl., Ph. Aus. and Ph. Ital. The new French Codex directs that it be prepared from the solid extract and the German directly from the drug representing 1 per cent. The U. S. P. is by far the strongest, as it uses 7 per cent. fluidextract by volume.
Syrupus Lactucarii.

I have already commented on this syrup in a paper before the New Jersey Pharmaceutical Association, 1909.

Syrupus Rosae.

I have already commented on this syrup in a paper before the New Jersey Pharmaceutical Association, 1909.

Syrupus Pruni Virginianae.

The present formula is not entirely satisfactory as the drug is not percolated to the extent that it should be for extraction, and there is an excess of glycerin used in this preparation. The results of experiments now being made on this syrup will be reported later.

Syrupus Senegae.

This is a sample of formula directed by the foreign pharmacopoeias to be made by direct infusion of the ground drug or percolation with weak alcohol.

Syrupus Tolutanus.

Several of the foreign pharmacopoeias have Syrupus Balsamum Tolutanum, and they very commonly direct that it be prepared from the balsam infused with water and sugar added to the filtered infusion.

The Chairman: Ladies and gentlemen, you have heard that excellent paper of our friend Beringer. Whenever Mr. Beringer writes a paper, he writes a good one. Now is there any discussion? I hope there will be. Mr. Dunning is one of these experts on Syrups.

Mr. Good: I wish to ask Mr. Beringer a few questions, and make some comments on these Syrups. First, as to the spelling of "Syrup" in the French Codex.

Mr. Beringer: The French Codex for 1908 gives simply "Syrupus."

Mr. Good: I have frequently had prescriptions from a French physician, and he spelled it "Sirop." I have had a great deal of satisfaction in the use of the present formula for Syrup of Almond, from the fact that I so rarely have a prescription for it, that making it in the old way I was obliged to retain the prescription for an hour or two before it would be completed.

Mr. Sass: I would like to ask Mr. Beringer if he has made any experiments as to Syrup of Hypophosphites.

Mr. Beringer: I think that the formula for that is absolutely impracticable. My remedy for that is to cut down the amount of sugar and increase the amount of water. That is the modification which I think will have to be made in that formula.

Mr. Sass: The experiments I have had with syrup of hypophosphites: We are making about 16 liters at a time, and have had a great deal of trouble. But since that time I have added 1 Cc. of lactic acid to each liter of the syrup and have had no trouble whatever. It keeps well. With the compound syrup of hypophosphites also I had some trouble. I found it necessary to increase the amount of sugar and decrease the water, because if you use the same amount of water it will make more syrup than the
Pharmacopoeia calls for. I used 810 Gms. of sugar instead of 775. Since that time I have had no trouble in keeping it. I also make about 16 liters at a time, and I get very clear, nice yellow-colored syrup. Once I kept a bottle for about eight months; I made it in winter and kept it until late in summer, and the syrup was just as clear and fresh as could be.

Mr. Dunning: I desire to speak a few words in reference to syrup of hypophosphites compound, because I am somewhat familiar with the question. I believe I suggested the present formula to the revision committee, but I did not suggest the amount of sugar directed in the formula. I think I suggested 850 Gms. of sugar, which makes a saturated solution. I believe this formula to be satisfactory as I have been using it for some eight or ten years, and have had no trouble, whatever. If the amount of sugar be reduced, then there will certainly be some precipitation and growth. If the sugar is increased, however, as this gentleman suggests, the water must be decreased; otherwise the volume will be greater than it should be.

Mr. ———: Then as to directions how the syrup should be made, I don’t think it necessary to say that this syrup should be made by percolation. You can not make it of the U. S. P. strength by percolation, because when the solution comes in contact with the sugar, and becomes saturated, a good deal of the hypophosphite salts will be left on the cotton. I think the proper way to make it is by adding sugar to the solution and shaking it until it dissolves, and then filter it. If you filter either one of these syrups then you will have a perfectly clear syrup.

The Chairman: The way I have been in the habit of doing is to have the solution perfectly clear first, and then you will have a perfectly clear syrup.

Mr. Cook: I have had considerable experience in making tincture of lactucaurium and difficulty in securing a suitable benzin. The tincture of lactucaurium on the market contains considerable resinous matter, and it is impossible to filter it out. On the question of benzin, there is considerable difficulty in getting this in a small way. A large dealer can go to a dealer in oil, and buy a quantity of it, but in order to buy by the quart or gallon it is almost impossible, in our experience. We can not buy from the wholesale houses. Several years ago we went into this question quite elaborately, and had one of our men go down to the refinery and there secure five gallons of this benzin. They drew it off in such a way, however, that the product was contaminated. They had a long pipe which they used to draw from many tanks of different degrees. We were compelled of course to redistill, and get the proper fraction, and this of course you can not do unless you have the proper apparatus for redistilling. It is questionable whether the process as it stands to-day should remain, if there is a process so simple as Mr. Beringer recommended as satisfactory.

The Chairman: In connection with this benzin question I might tell a joke, and that is that the Standard Oil Company has a big tank, with three taps to it. When you go there for benzin you get it out of one tap; for naphtha out of another, and for gasoline, out of a third; but they all come out of the same tank.

Mr. Beringer: I will say that now that the chemical manufacturers have taken up the subject of a purified benzin it has become a commercial article, and I think the pharmacist will find no trouble in getting it.

Mr. White: I make a motion that we receive the paper of Mr. Beringer, with thanks.

Motion seconded and carried.
A COMPARISON OF THE TINCTURES OF THE WORLD.

THE CHAIRMAN: The next paper is by Mr. E. F. Cook on "A Comparison of the Tinctures of the World.

Mr. Cook here read his paper, at the same time exhibiting a number of samples.

A COMPARISON OF THE TINCTURES OF THE MORE IMPORTANT PHARMACOPEIAS OF THE WORLD.

BY E. FULLERTON COOK, P. D.

For the purpose of comparing the formulas for tinctures in the United States Pharmacopoeia with corresponding preparations used throughout the world, the essential facts about each preparation, as it appears in the foreign pharmacopoeias, have been collected. This compilation includes the official Latin title, the title commonly used in the country where it is official, the number of grammes of drug in 1000 Cc. of tincture, the menstruum, the process for preparation, the standard by assay, if any, and identity tests. The pharmacopoeias examined are: United States, 8th Revision; Belgium, 1906: British, 1898; French, 1908; German, 1900; Netherlands, 1905; Japanese, 1907; Spanish, 1905; Swedish 1908 and Swiss, 1907.

DEFINITION.

The term tincture has long been recognized to mean an alcoholic preparation, containing the extractive matter or the active constituent of a drug. While this is the usual acceptance of the term, there have been many exceptions. In the pharmacopoeias of the world the title of tincture is applied variously to infusions, spirits, acid solutions, toothache drops, simple solutions of chemicals, etc.

Where the title has been used in a foreign pharmacopoeia for a simple infusion, as is in the Spanish, or for other preparations not strictly a tincture, they have not been included in this compilation, because there would be no corresponding tinctures in the other books.

PROCESS.

The United States and British Pharmacopoeias are the only books which give in detail, under each preparation, the directions for manufacture. There the effort has been made to complete each article so that it can be independent of any other article. In all of the other pharmacopoeias a general article precedes the class or is given elsewhere in the book, outlining the several processes and reference is then usually made under each tincture to the particular type process to be followed.

In the United States Pharmacopoeia the percolation process is directed in all instances where the material is adapted to such a process, arnica being an exception. For such drugs as aloes, tolu and myrrh which cannot easily be percolated, maceration is directed. In the foreign pharmacopoeias, however, maceration is usually given the preference and directed
to be used, excepting in those tinctures which were recognized by the
International Conference, where percolation was recommended. It is
ture, in some instances and in the Belgian and
Dutch Pharm., either process may be used in most cases, but percolation
has not been generally introduced.

IDENTIFICATION TESTS.

One of the peculiarities of some foreign pharmacopoeias which is not a
part of the text in any of the United States Pharmacopoeia articles, is the
introduction of identity tests based upon color, odor and taste. Such
identity tests are used in the French, Swiss, German, Japanese and Dutch
Pharmacopoeias. Another type of test given in the French, German and
Swiss Pharmacopoeias, under certain tinctures, is the effect when they are
mixed with varying proportions of water. In others the specific gravity is
given and in the Dutch the per cent. of extract when the tincture is
evaporated. In a few instances in those preparations which contain
chemical substances, chemical tests are included.

These identity tests, especially those of color, odor and taste, have
never found a place in the United States Pharmacopoeia and seem to the
writer to have little value. The difficulty in describing a color exactly, is
well known, and is illustrated by the difference in the description of the
same tincture in several pharmacopoeias. For example: Tincture of
Digitalis:

French: "Yellowish-green."
German: "Dark greenish-brown."
Japanese: "Brownish-green."
Swiss: "Green when fresh, later greenish-brown."

The possible variation in color is so great for normal drugs that an exact
shade can never be accurately described or demanded.

In the description of odor and taste the usual wording is "like that of
the Drug"; or "characteristic," "bitter," "spicy," etc. Such tests can
be of little value in establishing standards of strength or purity, and the
United States Pharmacopoeia has wisely excluded them.

ASSAY.

Assay processes are only given in a few cases in the foreign pharma-
copeias, although where the International Conference has adopted an ass-
ay standard, this standard is usually a requirement.

INTERNATIONAL STANDARDS.

The influence of the standards adopted by the Brussels Conference, of
1902, for potent remedies, is well illustrated in this class of preparations.
Twenty-eight of the tinctures in the United States Pharmacopoeia were
changed in strength to correspond to the international standard and prac-
tically all of the pharmacopoeias of the world, which have been revised
since 1902, conform to those standards.
The numerous changes in the United States Pharmacopoeia were for the purpose of securing a compliance with the general principles adopted for tinctures at that Conference: namely, that all tinctures of potent or active medicinal substances should contain 10 grammes of the drug in 100 Cc. tincture. All others to contain 20 grammes of drug in 100 Cc.

It may be of interest to mention that in the British Pharmacopoeia the drug strength is so adjusted for tinctures that there may be a uniformity in the dosage. I desire to acknowledge assistance in translation of M. S. Cook, H. S. Cook and O. W. Osterlund.

The compilation herein described, covering about 100 pages, was, by motion in the "Section," referred to the U. S. Pharmacopéal Revision Committee, since it was too elaborate to reproduce in the "Proceedings" in its original form, and an abstract would be impracticable, the compilation itself consisting of abstracts from the Pharmacopéias mentioned.

The Chairman: You have heard the paper of Mr. Cook; it is before you, and also the samples. He has done some very good work for the Pharmacopéal Revision Committee, and the profession at large.

Mr. Beringer: I have always said that strophanthus should be exhausted first of all with purified benzin. Of course you cannot extract the fat entirely.

The Chairman: I have always had that very same idea, that extracting the oil from strophanthus with petroleum benzin is preferable to ether; in fact, I am making the two tinctures at present and much prefer the former. I have a number of physicians interested in it, and have been experimenting with it and find it makes a clearer tincture. I found that there was a statement to the effect that tincture of strophanthus should be made with 70 per cent. alcohol, but must not be diluted; so experiments along that line ought to be carried out.

Mr. Good: I would like to ask Mr. Beringer if he has had any experience with the idea that Mr. Wilbert advanced in making tincture of digitalis—by making it in the ordinary way, and then putting the tincture on ice and filtering it while cold, getting the fat out in that way?

Mr. Beringer: I follow the process very largely of extracting the powder with purified benzin, and then drying it. In addition to that there is a certain amount of ammonia added. We sell a great deal of it, and it is being very highly commented on by physicians.

Mr. ———: I can corroborate what Mr. Beringer says, that tinctures made from the same drug, both with the benzin extraction and without the benzin extraction, test up equally well. There is no apparent difference. With regard to making tincture of arnica, it is my understanding from the Pharmacopoeia that the process can be altered, provided the same result is obtained. It seems to me it is perfectly proper for you to make the official tincture of arnica by percolation, if you so desire.

Mr. ———: I move that the paper be referred in the usual way

The Chairman: I think the paper is too important to be treated in the usual way.

Mr. Lawall: I move that it is the sense of this Section that it be accepted, with thanks, and be referred to the Revision Committee.

Carried.
General Secretary Caspari: The Section has just taken action on this paper of Mr. Cook, and referred it to the Revision Committee. I want to ask if it is the sense of the Section that the paper as presented, which is of course a very voluminous statistical report, shall be published in the Proceedings as it is, or shall it simply be referred to, and the paper itself given to the Revision Committee.

The Chairman: The paper itself, as I understand, will be accepted and turned over to the Publication Committee who will have to decide whether or not it is too voluminous to be printed in full in the proceedings; I hope it will not be considered too voluminous for that purpose.

Mr. ——— : I think it would be unwise for us to instruct the Secretary to print this. The failure to have it printed would in no wise detract from our appreciation of the value of the paper, since it will be practically of no grave importance except to the Committee on Revision; and I think that the printing of a summary of it, such as the Secretary will be able to prepare himself, or obtain from Mr. Cook, would probably serve the purpose. Ordinarily the paper would be referred to the Secretary without instruction, but inasmuch as the Secretary has asked for instructions, I take it we should comply with his request. I am sure the paper in its entirety would not be of much value to a large number of pharmacists as to justify devoting so much space to it in the printed Proceedings. The value of it will be most especially to the Committee on Revision. So, therefore, I move that it be the sense of the Section that the paper be referred to the Committee on Revision, as has already been done, but that we do not deem it essential that it should be printed in full in the Proceedings. I want to make it quite plain that this reference on my part does not mean any lack of appreciation of the work.

Mr. Beringer: I would ask to be allowed to make an amendment to that motion. I think we should request the Committee on Publication to publish at least an abstract of the paper, if not the entire paper.

The Chairman: It has been regularly moved and seconded, that the paper be referred to the Publication Committee, and it is our intention to have it published in abstract.

Carried.

The Chairman: Now the Nominating Committee is ready.

Mr. Dunning: Inasmuch as Mr. Ladish has expressed a desire that he be not considered for office in this Section, and as Mr. White, unfortunately, is ineligible, because he has retired from the retail drug business, we suggest and nominate Mr. Louis Saalbach, of Pittsburg, for Chairman; Mr. P. H. Utech, of Meadville, Pa., as Secretary; and Mr. W. A. Hall, of Detroit, as Associate.

We do not make any recommendation as to the point I am about to bring out; but we want to call attention to the fact that there are a great many members that are not eligible for nomination for office in this Section, though they are most suitable, because of a by-law which requires them to be actively connected with the retail drug business; and we think this point might be taken into consideration. We observe that nearly half the papers that have been submitted to this Section at this meeting, have been presented by men who are not eligible to office. We simply make that as a suggestion for future consideration by the members.

Mr. Ladish: I should like to know if Messrs. Saalbach and Hall know about their being placed in nomination? For this reason: Out in California last year, the com-
mittee went around begging people, and got down the names of men who did not belong to the Association, and then got them all from one little part of the country. Now if you select a man without getting in communication with him beforehand, you may find that he is tied up in some way, and you cannot expect good work from a man of that sort. It would be unfair and entirely uncalled for to place a man in a position where he must do a lot of work, when he has no time to devote to it, and it is an injustice to the man himself. Another thing is about the point Mr. Dunning spoke of. The reason the practical pharmacist is not interested in this is, you frighten him away. You want to encourage these people. You cannot expect a practical pharmacist, who is hampered by the details of his store and the condition of his cash register, to give the same attention to these matters as the man who deals entirely with the other side or phase of his profession. The thing to do is to encourage these people all we can, even if their contributions be ever so little; because as has been pointed out here repeatedly, the salvation of the entire drug business concentrates on the practical pharmacist. And as was pointed out a little while ago, you want these men on the Revision Committee, too. So far as I am concerned it don't make any difference, one way or the other, but you cannot possibly expect to make progress if you are going to keep away the fellows you want. I think it is one of the most important things to be considered to-day, how you are going to get the practical pharmacists interested in this work.

MR. LAWALL: Mr. Chairman, I am not a member of the Nominating Committee, and am not a retail pharmacist, but the nominees of the committee, so far as Chairman and Secretary are concerned, are men with whom I am personally acquainted. Mr. Saalbach, it is true, is a teacher, but his interests are in the retail business in Pittsburg, being a joint owner with his brother. He is a man furthermore who, when he takes up any committee work, does his full duty by the committee with which he is connected, because he has been on committees of which I have been chairman; and I know that he has done good work in his Pennsylvania Association. Mr. Utech is a man who is practicing exclusively, in Meadville, Pa. He has presented several papers at this year's meeting of the Association, and other papers in previous years. He is a constant contributor to pharmacy, and he is another man who always does committee work well when it is entrusted to him.

MR. MAYO: It happens that I am ineligible, under the retail clause, so I can speak from a neutral standpoint. As Mr. Ladish has stated we must get the retail druggist interested if we can, by accentuating the retail drug side, and we ought to do it, and I hope no change will be made in that requirement.

THE CHAIRMAN: I want a correction in that report of the Committee. I will not have any fight with Mr. Dunning, about the teachers, and so forth, predominating, because I wanted the practical pharmacists to predominate, and if you will look over this program you will find that among the 58 papers which were read 29 or 30 were from actual, retail pharmacists. Of course I include Professor Dunning and Professor Hynson, as retail druggists. It is the pharmacist who is very slow in waking up, and a great many pharmacists, as Mr. Ladish says, have not the time to write papers, even though they have the talent, but they can take part in the discussion of them. That is one statement I would like to have corrected, and the program will show I am right.

MR. DUNNING: The reason I brought this matter up is that there are a great many men who have been retail pharmacists for many years and have subsequently become disconnected from it for some reason or another—such as entering into the teaching department of pharmacy, or they may have become connected with some manufacturing concern. That does not mean that they are not familiar with the problems of retail
pharmacy, and that they are not capable of understanding those problems, or that they are not suitable for office in this Section.

Mr. Ladish: I don't think there is any use in prolonging the discussion; I think it would be just losing time; I believe the by-laws are all right as they are now, and I would like to move you that this report be received; that the nominations be closed, and that the Secretary be authorized to cast the ballots of this Section for the nominees.

Mr. Wilbert: I second that motion.

Motion carried.

The Secretary: I take pleasure in casting the ballot of this Section for the election of Louis Saalbach, of Pittsburg, as Chairman; P. H. Utech, of Meadville, Pa., for Secretary; and W. A. Hall, of Detroit, Mich., as Associate.

Mr. Wilbert: I think it is due to the present officers that we give them a vote of thanks. Those of you who were here last evening I am sure appreciate the able work of our Chairman for his most unique symposium on the National Pharmacopoeias. Those of you who were not here I am sure have lost something and will have to wait a long time for anything as good. I move, therefore, that we extend a rising vote of thanks to our outgoing officers for the good work they have done for us.

Motion seconded and carried.

The Section here, upon motion, adjourned, there being no further business before it.

Papers read by title:

EXPERIMENTAL WORK IN PRESSURE PERCOLATION.

BY HILAND FLOWERS, NEW YORK.

In submitting the experimental work by pressure direct,—namely, by pressure upon the menstruum and drug arranged in a cylinder or tube by an air-tight piston, the writer would preface the account of the results herein submitted with a brief outline of general interest. Not that it is to serve as an excuse for shortcomings or as an apology—for the writer does not have in mind that either excuse or apology is needed—the process will either commend or defeat itself.

Since Count Real's attempt at pressure percolation with his column 12 feet in height the attempts at pressure percolation have been many and world-wide. This year, 1910, there have come reports from Turkey and from Germany of results by pressure percolation. The apparatus illustrated herewith was made and used by the writer in 1881 to 1884 in New Orleans for the percolation of ginger. It was demonstrated before the New York Branch of the American Pharmaceutical Association February 7, 1910, published in the American Druggist for February 14, 1910, and noted in the Bulletin of the American Pharmaceutical Association for March 1910. In view of the reawakened interest in the subject the writer deemed it his duty to attempt further experiment, however imperfect, or
under whatever improvised condition, and submit the results to the members of the American Pharmaceutical Association.

Many pharmacists have as many ideas as to the exhaustion of drugs either by percolation or maceration, and no doubt all the processes are good; hence each new suggestion must take its place, as no hard-and-fast lines could be drawn with any degree of assurance of general acceptance. The process of maceration, old and new school, has its adherents, its champions and its data of accomplishments. To advance the theory that maceration is the process of forces of nature pressing the liquid to point of least resistance, and that pressure applied direct with increased power will accomplish the same results, would open the subject to the scepticism of both schools.

Percolation is atmospheric pressure forcing the liquid to the point of least resistance. Capillarity is nature's process of forcing the liquid to the point of least resistance, upwards, downwards, sidewards, or all at one and the same time. The atmospheric pressure is approximately between fourteen and fifteen pounds to each square inch. In the adoption of a method of percolation by pressure direct, the atmospheric pressure is increased or decreased at the will of the operator, and the process of maceration, percolation, capillarity, displacement, lixiviation and filtration is conjointly brought to the point of individual control. In the process of applying pressure direct by piston or compressed air the operation of percolation may be suspended, intermittent or continuous, as the operator may find by experience to be the most advantageous in bringing the drug most effectually under control.

Whether the three samples submitted of experimental work under pressure percolation measure up to the required standard of assay excellence, or not, the results cannot detract from the merit the process may have, for it must be kept in mind that the disadvantages under which these three were produced might offset any deficiency of assay requirements which under more advanced and perfected conditions should produce results which would measure the full assay requirement of excellence. The writer submits what improvised experimental work has accomplished; the fact that any product can be produced by the process of direct pressure percolation is worthy of attention and interest sufficient to warrant, if not demand, further and exhaustive investigation as to the percolation by pressure direct.

To enter in this paper into any discussion as to the merits of the process seems to the writer needless, for should the process prove effective it would obviously demonstrate its own advantage, it will tend to, if not wholly to standardize tinctures and fluidextracts and give confidence to the physician as to the uniformity of same. Under pressure percolation the process of making tinctures and fluidextracts will be under a definite rule—a given amount of menstruum having a given alcoholic strength and
specific gravity, a given quantity of drug of stated fineness and assay, under pressure direct, whether or not of limited pounds of pressure, should yield a definite quantity of percolate of a given specific gravity and alkaloidal assay.

The tincture of opium submitted with this paper was made by pressure percolation in twenty-five minutes; the sand used was suggested by Mr. Raubenheimer, who said its use in preparing tincture of opium was recommended by the Danish Pharmacopœia. The tincture of strophanthus, submitted with this paper, was made in twenty minutes according to the United States Pharmacopœia as to menstruum and drug. The tincture of nux vomica was made in ten minutes. The United States Pharmacopœia calls for tincture made from solid extract; this was made from the powdered drug. The percolator used was a metal cylinder or tube with an air-tight piston obtained from a six-ounce metal syringe, hand-pressure only being used. The samples submitted were made at the laboratory of Mr. Raubenheimer, 1341 Fulton street, Brooklyn, N. Y., and entered upon his label is a description of each. The drugs were first weighed by Mr. Raubenheimer, then handed to me. The alcoholic menstrua were prepared and measured by Mr. Raubenheimer. The powdered opium and powdered strophanthus were purchased from a wholesale drug house in New York City; the nux vomica was taken from stock.

The formulas for the tinctures are as follows:

Tincture of Opium.

<table>
<thead>
<tr>
<th>Pulverized opium, 60-mesh fine</th>
<th>10 Gm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sand</td>
<td>50 Gm.</td>
</tr>
<tr>
<td>Alcoholic menstruum, 50 per cent</td>
<td>120 Cc.</td>
</tr>
</tbody>
</table>

The powdered opium and sand were mixed in a dry state. A layer of absorbent cotton was packed firmly at the bottom of the cylinder or percolator, 10 Gm. of sand was then placed on top of the cotton and the prepared powdered opium was packed loosely in the tube and one-half of the menstruum was poured onto the drug, the piston inserted and the liquid forced through. The product was a dark percolate; the remaining menstruum was then poured on the drug and forced through, yielding a lighter percolate. The total amount of percolate from 120 Cc. was 95 Cc. Time, twenty-five minutes in the two processes. Estimated pressure, 100 to 150 pounds.

The first attempt to exhaust the opium without sand failed with a small hand machine; the pressure required would reach far beyond any hand power.

Tincture of Strophanthus.

<table>
<thead>
<tr>
<th>Powdered strophanthus (40 mesh fine)</th>
<th>10 Gm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alcoholic menstruum, 70 per cent</td>
<td>100 Cc.</td>
</tr>
</tbody>
</table>

The absorbent cotton was placed in the bottom of the percolator, the
powdered drug, moistened by a small quantity of menstruum, was packed firmly in the percolator, the menstruum poured upon the drug and the

Flower's Pressure Percolator.

A A, air vent in upper screw cap; BB, hollowed thumb screws to permit air to enter below piston; C, rubber washer fitted between piston plates; DD, upper and lower plates of piston screwed together independent of hollowed thumb screws; E, tripod support with screw attached; F, lower screw cap; G, perfected diaphragm on which cotton rests.

piston inserted and forced through, yielding 90 Cc. of percolate; the pressure was estimated at 75 to 100 pounds. The marc is submitted with sample.
Tincture of nux vomica.

Powdered nux vomica (40 mesh fine) .................. 10 Gm.
Alcoholic menstruum, 75 per cent .......................... 100 Cc.

The absorbent cotton was placed in the improvised percolator; the drug previously moistened was packed firmly and the remaining menstruum poured in, the piston inserted and the liquid pressed through. The process yielded 90 Cc. of percolate. The writer was not satisfied to submit this percolate first obtained, so repacked the drug and again passed the percolate through the drug. Time, about ten minutes at a pressure of about 75 pounds.

The writer is indebted to Mr. Otto Raubenheimer for his kindness in preparing the samples submitted.

The accompanying cut of the pressure percolator, taken from the American Druggist of February 14, 1910, and description of same, are self-explanatory.

The powdered drugs used in the preparation of these samples were 60 or 40 mesh fine. Opium 60 mesh, Strophanthus and Nux Vomica 40 mesh. It is the opinion of the writer that for the preparation of tinctures and fluidextracts more exhaustive results would be secured if the drug were 60, 80 or 100 mesh fine. In the case of tincture of nux vomica where the pressure was 75 pounds, and the tincture of strophanthus, where the pressure was 75 to 100 pounds, a powdered drug 40 mesh fine requiring a pressure of 75 to 100 pounds does not yield as good results as finer powder, even though at higher pressure.

QUALITY OF SOME CRUDE DRUGS EXAMINED DURING 1909.

BY HERMANN ENGELHARDT.

There is no doubt that the Pure Food and Drugs Act has had a decided influence on the quality of the official drugs. While the percentage of drugs which were rejected in this laboratory during 1909 was considerably lower than it was in former years, the following results dealing mostly with the examination of alkaloidal drugs and of some gum resins will indicate that inferior products cannot be altogether eliminated from commerce.

Aconite Root.—No difficulty was experienced in obtaining aconite root of the proper percentage—viz., 0.5 per cent. ether-soluble alkaloids.

Belladonna Root.—Of 36 samples examined during the year we were compelled to reject 14, which came below the required standard of 0.5 per cent. of total mydriatic alkaloids. Some of these samples assayed as low as 0.14 per cent., .19 per cent., .29 per cent., .37 per cent. of total alkaloids.

Belladonna Leaves.—31 samples out of 34 showed an alkaloidal strength higher than required by the U. S. P. Three barely came up to the re-
requirements and as a drug with a higher percentage of alkaloids is obtainable, these three were rejected. In this connection reference should be made to the examination of belladonna cultivated in California, which, however, commanded a considerably higher price than the belladonna on the market. The following results were obtained: Stems, .85 per cent., leaves, .83 per cent., mixtures of stems and leaves .79 per cent. of total alkaloids.

*Cinchona.*—Of 39 samples examined, 7 had to be rejected, 2 of them assaying as low as 2.9 per cent., and 3.76 per cent. of total alkaloids.

*Cinchona, Red.*—17 samples were examined of which 2 were rejected, not coming up to the alkaloidal strength.

*Colchicum Seed.*—Considerable difficulty was experienced in obtaining good material. 20 out of 26 samples were inferior to the requirements of the U. S. P., some assaying as low as .24 to .25, .22 per cent. etc. of colchicine. These samples were examined strictly according to the U. S. P. process, which as it was pointed out in various communications from this laboratory gives results which are decidedly too high (40 per cent). If the new Pharmacopoeia should adopt a purification process of the colchicine obtained by the U. S. P. method, the standard for colchicum seed—viz., .45 per cent. of colchicine must be considered as too high and should consequently be reduced.

*Colchicum Root.*—Only 2 samples out of 13 did not come up to the official strength. As to the purity of the resulting colchicine, the same must be said as mentioned under colchicum seed.

*Conium Leaves.*—There is no reason for retaining this obsolete drug in the Pharmacopoeia, inasmuch as all the samples which were examined in this laboratory had to be rejected, as they contained scarcely any conine. This is due to the volatile character of the alkaloid and to the fact that the leaves usually arrive in a broken and almost powdered state.

*Coca Leaves.*—The samples and shipments fully came up to the required strength—viz., .5 per cent. of ether-soluble alkaloids. We received a few large shipments which contained more than 1.25 per cent. of ether-soluble alkaloids.

*Ergot.*—The quality of the ergot examined during the year was very good. Only 9 out of 34 samples showed a deficiency in chemical and physiological strength.

*Henbane.*—One out of eleven samples assayed below the required strength.

*Ipecac.*—This drug has been of decidedly better quality than in previous years. Of 9 samples examined only one assayed slightly below 2 per cent. of total alkaloids.

*Jalap.*—While in former years it was difficult to obtain a drug with the required 8 per cent. of total resin, a fact which compelled the U. S. P. to reduce the standard for this drug to 7 per cent. of total resin, we have not
encountered any difficulty in obtaining jalap of the required strength. Of 15 samples examined only 4 were inferior in resin. Jalap with more than 12 per cent. of resin was easily obtained during the year.

_Jaborandi_.—The quality of this drug was excellent. We received samples and shipments with as much as 1 per cent. of total alkaloids.

_Kola Nut_.—It has been recommended on various occasions to assay this drug, which is not official. The samples examined during the year 1909 were of a very good quality, assaying from 1.5 per cent. to 2 per cent. of caffeine.

_Nux Vomica_.—While samples with 3½ per cent. of total alkaloids were not infrequent, we received four samples out of 17 which did not come up to the required percentage of strychnine.

_Scopola_.—The quality of scopola has been very poor during the year 1909. 11 samples out of 15 had to be rejected, assaying less than .5 per cent. of total mydriatic alkaloids. In former years we did not experience any trouble in obtaining scopola root with as high as .7 to .8 per cent. of alkaloids. The low percentage of the drug offered on the market at the present time may be due to an adulteration of scopola root with the root of scopolia japonica which is decidedly lower in alkaloidal strength.

_Scammony_.—The supply of the exudate and the true root seems to be nearly exhausted, while large quantities of Mexican root are offered on the market. An article dealing with this subject will be read at this meeting.

_Stramonium_.—There was no necessity for the Pharmacopœia committee to reduce the standard for this drug. Only 2 out of 20 samples assayed below the official standard, while fully 70 per cent. assayed much higher, e. g., .40 to .45 per cent. total alkaloids.

_Cudbear_.—The coloring power of this drug is not always satisfactory and it would be advisable for the new Pharmacopœia to adopt a method for standardizing it.

_Cochineal_.—As several reliable methods of determining the coloring power of this drug are available, it cannot be too strongly recommended that the next Pharmacopœia adopt a standard for cochineal in order to exclude the inferior products which are met with on the market.

In conclusion a few words may be said about _Asafetida_ and _Guaiac_. 15 out of 28 samples of asafetida had to be rejected, being inferior in content of alcohol-soluble matter and yielding too high a percentage of ash. 4 out of 9 samples of guaiac had to be rejected for the same reasons.

MODIFICATION OF SYRUP OF FERROUS IODIDE.

BY WILLIAM C. TOPLIS, PHILADELPHIA, PA.

The syrup of ferrous iodide, as directed by the U. S. Pharmacopœia, requires the use of iron in the form of bright wire cut in small pieces.

The preparation of the syrup, by this requirement, is delayed unneces-
sarily, thereby exposing the solution of ferrous iodide to prolonged risk of oxidation, in addition to consumption of time devoted to the purpose.

For these reasons, I would recommend the employment of reduced iron instead of bright iron wire cut in pieces.

This recommendation also requires a slight deviation from the handling as directed for the use of iron wire, because the reaction between the iodine and the iron (reduced iron) is so prompt that the heat generated, accumulates more rapidly than it is dissipated. In order to compensate for this condition, the following procedure does well.

Select a flask of ample size. Into the flask, pour all of the water and all of the iodine, lastly small successive portions of the reduced iron, with constant agitation, allowing a short interval between each addition. The heat generated, is promptly dissipated, especially so if the flask used be very large.

The temperature, during the reaction, may thus be perfectly controlled, and the time reduced to a minimum. My observation, on the time required, is eight minutes from start to finish, ready for filtering upon the sugar. The filtrate is beautifully green in color, without a trace of free iodine. This observation was noted on a finished quantity of five hundred cubic centimeters.

Later observations on larger quantities in the hands of my assistant, proved equally successful, yielding a product conforming to the pharmacopœial requirements, to the last detail, and finished ready for use, easily within an hour.

One other difference which may be of some importance is the fact, that reduced iron is a more pure form than the commercial variety, thus avoiding unknown side reactions, that might exert some undesirable influence upon the finished product.

TERPIN HYDRATE—A PERFECT SOLUTION AND SATISFACTORY PREPARATION OF SAME.

FRANK W. A. HAIN, NEWARK, N. J.

The first request for a solution of terpin hydrate to be given in mixtures, etc., came to me about ten years ago, when a physician desired information on the solubility of same.

An emulsion, containing two grains to the fluiddrachm, was about the most satisfactory mixture we could obtain at that time. However, it set me experimenting with terpin hydrate, and finally resulted in the following formula:

SOLUTIO TERPIN. HYDRAT. COMPOS.

Terpin hydrate powd. ........................................ 30 Gm.
Hot glycerin .................................................. 650 Cc.

Stir until dissolved. When partly cooled add:
FLUIDEXTRACT WILD CHERRY BARK.......................... 62.5 Cc.
Alcohol .................................................. 235 Cc.
Glycerin .................................................. sufficient to make 1000 Cc.

Dose:—4 Cc. containing 0.12 Gm. (about 2 grs.) terpin hydrate to be taken with water. To meet climatic conditions I found it advisable, however, to reduce the amount of terpin hydrate to 25 Gm. per 1000 Cc., the resulting preparation containing 0.1 Gm. (about 1½ grs.) per 4 Cc. of terpin hydrate in perfect solution.

Codeine or heroin in the usual amounts are readily dissolved in the alcohol before adding to the mixture.

The Pharmacopoeia mentions the solubility of terpin hydrate in water (hot and cold), alcohol (hot and cold), ether, chloroform, and glacial acetic acid. Why not add the solubility in glycerin and practical application of same?

ELIXIR OF IRON, QUININE AND STRYCHNINE PHOSPHATES.

ADOLPH F. MARQUIER, NEWARK, N. J.

The formula for my preparation is as follows:

Ferric phosphate soluble .................................. 32.0 Gm.
Quinine phosphate ........................................ 8.5 Gm.
Strychnine phosphate ...................................... .24 Gm.
Oil sweet orange ........................................... 2.0 Cc.
Alcohol ..................................................... 250.0 Cc.
Glycerin .................................................... 300.0 Cc.
Water, a sufficient quantity to make .................... 1000.0 Cc.

Directions.—Dissolve the ferric phosphate in 300 Cc. of distilled water; by maceration (cold), the strychnine and quinine phosphates and oil of orange in the alcohol; add to this the glycerin, and lastly the iron solution; allow to stand 24 hours, if possible, and filter.

This preparation will mix with water in all proportions without precipitation, and retains its green color even though exposed to light, the cost of ingredients is no more, if anything less than the present official preparation.

Since its introduction it has met with great approval by the medical profession in our state, having had many requests for its formula.

SOME U. S. P. PREPARATIONS.

BY JOHN K. THUM, PH. G., PHILADELPHIA, PA.

LIQUOR MAGNESII CITRATIS.

The formation of fungi in this preparation after it has been made a short time is a most frequent occurrence. Yet in the directions contained in the Pharmacopoeia for the manufacture of this popular preparation the fact that micro-organisms may, or do develop, is entirely ignored. Of
course the Pharmacopoeia states that "this solution should be freshly prepared when wanted," but every practicing pharmacist knows that this is impracticable to say the least. It must be kept on hand for immediate dispensing.

Recently boiled and filtered water is recommended by some as a solution of this problem, but this is only a half-measure, or, to be more exact, it only postpones the inevitable result for a few days. To be brief, the question is a bacteriological one, and the answer is absolute and complete sterilization by heat. This point also emphasizes the need and desirability of a chapter devoted to sterilization in the coming revision of the United States Pharmacopoeia.

It has been our custom for some time to sterilize our solution of magnesium citrate in the manner described below, and we are firmly convinced that it is the only legitimate and practical way of obtaining a satisfactory preparation from every standpoint. Special or elaborate apparatus is not needed for any work of this kind the pharmacist may want to do in his laboratory or behind his prescription counter.

Ordinary citrate bottles with washer stoppers are used. They are thoroughly cleaned, inside and out, filled completely with water, placed in a deep agate kettle and the stoppers allowed to hang at the sides of the bottles so as to insure their being immersed in the boiling water; the kettle is then covered and boiling carried on for 30 minutes. (We have observed that boiling for 15 minutes is ample when every attention is paid to detail.) At the end of that time the bottles should be emptied and immediately stoppered. In the meantime the solution is prepared and filtered; each bottle is then filled, allowing, of course, enough space for expansion of the solution due to heat. The bottles are now replaced in the kettle and it is filled with water, taking care not to have the water come too near the mouth of the bottles; if this precaution is not taken the water will, in the process of ebullition, dilute the solution. Boiling is then carried on for 30 minutes, the bottles immediately stoppered, labeled, and stored away until needed for dispensing when the requisite amount of potassium bicarbonate is added.

Syrupus Ferri Iodidi.

The addition of dilute hypophosphorous acid as a preservative to this preparation as recommended by the Pharmacopoeia is not only objectionable but unnecessary. Objectionable because it preserves it too well; the instability of ferrous iodide is what makes it of value as a therapeutic agent. The physician is certain of its decomposition in the human body and the consequent absorption and assimilation of the resulting iodine by the patient.

A preservative, if it does not prevent this decomposition, at least retards it very materially. An uncorked bottle of the U. S. P. syrup of the iodide
of iron exposed to the usual temperature of the laboratory for the last six months shows no signs of the presence of free iodine; this is significant to say the least.

It seems to the writer that the use of the preservatives in medicines as well as in foods should not be encouraged by pharmacists.

We have been able to make a very fine syrup of iodide of iron which keeps very well and does not liberate any free iodine by the simple expedient of doubling the amount of iron wire.

The working formula is as follows:

Iron, in the form of fine bright wire cut in small pieces ...... 25.0
Iodine ................................................................. 41.5
Syrup. .................................................................
Distilled water, of each, a sufficient quantity to make ...... 1000 Gms.

Introduce the iron into a flask of thin glass having a capacity of 500 Cc. and wash well with water several times, then add to it 150 Cc. of distilled water, and afterwards the iodine. Shake the mixture occasionally and when the solution has acquired a greenish color and is free from the odor of iodine boil it for five minutes. Then filter it through a folded filter paper placed in a funnel, the point of which dips below the surface of 700 grams of syrup contained in a tared vessel. When the liquid has run through, wash the flask and filter with a mixture of 25 Cc. each of the syrup and distilled water previously heated to the boiling point, then remove the funnel and add sufficient syrup to make the product weigh one thousand grams. Keep the syrup in small, well-stoppered bottles.

**GRAY'S GLYCERIN TONIC COMPOUND; ORIGINAL FORMULA.**

P. HENRY UTECH, PH. G., MEADVILLE, PA.

On account of the wide publicity attained by the preparation bearing the above title, and in view of the fact that many different formulæ have been suggested, from time to time, as being identical with the original recipe, I take pleasure in presenting herewith the authentic formula of said Gray’s Glycerin Tonic Compound as prepared for, and prescribed by the late Dr. John P. Gray of Utica, New York.

This formula was originated in 1880 by Mr. Charles F. Hurlburt, a pharmacist of Utica (now deceased) at the request of Dr. Gray, who was at that time Superintendent of the New Yore State Hospital in that city. Having had frequent occasion to use a good stimulating stomachic tonic in his official practice, he instructed the said Mr. Hurlburt to prepare a palatable compound, containing such drugs as might be suitable for the purpose, enumerating such as he thought might be advantageous. As per his instructions the following preparation and modus operandi was devised:

First prepare the following:
SPIRITUS ÆTHERIS NITROSI.

Concentrated Tincture.

Gentian root ...................................................... 3 ozs.
Taraxacum root.
Bitter orange peel .............................................. 4 ozs.
Caraway seed.
Coriander seed .................................................... 3 dr.
(All in No. 40 powder).
Diluted alcohol, sufficient to make .......................... 2 pints.

Mix and percolate in the usual way to make 2 pints of tincture.

Next prepare as follows the

Elixir of Gentian, Taraxacum, and Phosphoric Acid.

Concentrated tincture ............................................. 16 ozs.
Alcohol ................................................................. 20 ozs.
Water ................................................................. 48 ozs.
Simple syrup ......................................................... 44 ozs.
Phosphoric acid, 50 per cent ................................. 3 ozs.

Mix alcohol, water, and tincture together; then add syrup, previously mixed with the phosphoric acid, and filter.

Finally, to make the finished product.

Elixir of gentian, taraxacum and phosphoric acid.
Glycerin.
Sherry Wine ......................................................... of each 8 pints.

Mix. Allow to stand 48 hours. Then filter.

SPIRITUS ÆTHERIS NITROSI.

BY EWING R. COCKE AND C. A. DUNCAN.

Sweet spirit of nitre is defined by the U. S. P. as an alcoholic solution of ethyl nitrite yielding, when freshly prepared and tested, not less than 4 per cent. of the ethyl nitrite. It is evident from this definition that this preparation is not permanent and that only when freshly prepared will it come up to the U. S. P. requirements.

Several samples bought on the open market were assayed and were found to vary in strength from 2.26 per cent. to 3.45 per cent. They were acid to litmus paper and effervesced on addition of crystals of potassium bicarbonate.

When freshly prepared, this preparation is slightly acid in reaction. This can be prevented to a considerable extent by the addition of 5 per cent. glycerin. A sample made in this manner stood for three weeks before showing trace of acidity. Exposure to light for a longer period developed further acidity but apparently not to the extent of U. S. P. preparation. The U. S. P. process directs that the ethyl nitrite, formed
by the reaction between sodium nitrite, alcohol and sulphuric acid, should be decanted into a separatory funnel and the water separated and discarded, then to be washed with cold water in which sodium carbonate is dissolved, this separated and then agitated with dried potassium carbonate.

We find that these two steps can be combined. The sodium carbonate which is to neutralize the acid and the dried potassium carbonate which is to remove the last traces of water will do this if the sodium carbonate and potassium carbonate are added at once and directly to the ethyl nitrite. Thus saving a washing and separating of ethyl nitrite and attendant loss by evaporation, etc. The ethyl nitrite is first carefully separated from the water, the sodium and potassium carbonate added, agitated for a few minutes and separated by filtering through cotton into a tared flask as directed in U. S. P. process. This method saves time, loss by evaporation and ethyl nitrite that is soluble in water used in washing.

**SYSTEMATIC OBSERVATIONS ON PEPSIN AND PEPSIN PREPARATIONS.**

BY C. F. NIXON.

Various questions have arisen in late years relative to the digestive value of pepsin, and especially of the pepsin preparations. Ten years ago these doubts did not exist to any extent, but as time went on the physician who hoped for digestive action, confined himself to Pure Pepsin or possibly the Essence of Pepsin. The other preparations, whether National Formulary or proprietary, were used chiefly as vehicles or placebos.

Three years ago it occurred to the writer to investigate the subject, and to answer these questions so far as they may be answered by laboratory methods. The assays were made by the U. S. P. process. Four of the pure pepsins of the market were assayed, and all were found to conform to the pharmacopoeial standard.

Of the National Formulary preparations, the Essence, Elixir, Elixir of Pepsin and Bismuth, Compound Digestive Elixir, Liquor and Glycerite were assayed at intervals. When freshly made all were found to possess full proteolytic activity except Elixir of Pepsin and Bismuth. This left a residue of 5 Gm. of undigested albumin. Compound Digestive Elixir was found to possess no amylolytic activity. It may be said, however, that the amount of Pancreatin and Diastase in the formula is so small that none could be expected. Further assays showed that the alcoholic preparations lost about 10 per cent. of proteolytic activity in three weeks, about 20 per cent. in five weeks and were practically inert in one year. The Glycerite possessed full activity at the end of one year, and lost about 15 per cent. in three years.

Many of the proprietary preparations of pepsin, essences, elixirs, compound elixirs, powders and tablets were assayed, and their activity ranged from zero to 50 per cent., as compared with similar N. F. preparations. These proprietaries were taken from stock and were of unknown age.
A later question has arisen relative to the utility of rennin in essence of pepsin, N. F. It has been suggested also that the rennin is digested by the pepsin. It is presumably directed in the formula for its milk-curdling properties.

By a series of experiments it was found that .5 Cc. of essence of pepsin, N. F., would produce a firm junket with 250 Cc. of fresh milk at 38° C., in 15 minutes. At the end of 30 days it possessed its full milk-curdling properties, so that it cannot be said that the rennin is digested by the pepsin. A lot of essence of pepsin was made without rennin, and it was found that 4 Cc. would form a junket, under the conditions given above, with 250 Cc. of milk. It was further found that the proteolytic activity of the essence containing rennin exceeded that not containing rennin by only about 10 per cent. The writer would recommend that rennin be eliminated from the formula, as it adds but little proteolytic activity, and is unnecessary as a milk-curdling agent.

While essence of pepsin, N. F., is a most excellent preparation from a clinical standpoint, it is most unsatisfactory as a pharmaceutical product. The alcoholic content is not sufficient to keep it from souring, and the writer very soon found it necessary to increase the amount of alcohol in the formula from 50 Cc. to 120 Cc. This makes a product containing about 18 per cent. alcohol. This is the least amount used in any of the proprietary essences. In all of the assays stated above, the essence contained this added amount of alcohol.

A great source of complaint with the N. F. formula has been the difficulty of obtaining a bright, clear product. It filters very slowly, usually requires several filtrations, and for some reason, frequently again becomes cloudy. These difficulties are due partly to the presence of rennin, and partly to the use of lactic acid instead of hydrochloric acid. By the use of the corresponding amount of glycerite of pepsin, instead of pure pepsin, these difficulties are also very much lessened. An essence made on these lines was assayed, and found to possess the same proteolytic and milk-curdling properties as that made with lactic acid and pure pepsin. Moreover, hydrochloric acid is a normal constituent of the stomach, and is in many cases a valuable aid to digestion. If rennin is obtained in the formula, the name should be changed to compound essence of pepsin, which would be undesirable.

I would recommend the following formula for essence of pepsin. It is quickly made, with one filtration, remains bright and clear, and does not differ materially in taste or appearance from the present essence.

Take of

</table>
Mix. Dilute the alcohol with 175 Cc. of water, add the glycerite, wine, and syrup. Rub the tincture with the purified talc, add the mixture of fluids gradually and filter. If necessary add enough water through the filter to make 1000 Cc.

Glycerite of pepsin, N. F. is an excellent preparation both for making of elixirs and essences, and for use in prescription compounds. It is, however, unfortunately often prescribed with strong alcoholic tinctures, with too large amounts of hydrochloric acid and with alkalies, chiefly sodium bicarbonate. With all of these the digestive activity of the pepsin is certainly inhibited, and probably destroyed. By the assay process, I have found that no digestion takes place after 24 hours, in mixtures containing 40 per cent. of alcohol, 2 per cent. of hydrochloric acid, or 3 per cent. of sodium bicarbonate.

It is the writer’s belief that when pepsin will digest 3000 times its weight of hard-boiled egg albumin in a test tube, it must be of digestive value in the stomach; and that unsatisfactory clinical results have been due to the use of alcoholic preparations of unknown age, and to incompatible mixtures.

EXPERIMENTS WITH ELIXIR DIGESTIVUM COMP. N. F.

BY HENRY C. BLAIR, PHILADELPHIA, PA.

Elixir digestivum compositum has been criticized adversely by so many men of reputation in scientific circles that a practical pharmacist hesitates to express an opinion. In fact he has been led to believe that this preparation is almost useless and a monstrosity pharmaceutically and therapeutically and that it should be left out of our books of standards.

Everyone criticises the variation in color which can easily be remedied by macerating cudbear in the elixir instead of using the tincture.

Pharmacists tell us that the majority of physicians in this country use elixir digestivum compositum or some similar preparation of mixed enzymes extensively; and physicians say that the results they get by using these preparations warrant them in continuing to prescribe them.

Believing these to be the facts and that there must be some digestive properties in this elixir even when it is old and even though scientists advise otherwise, the writer decided to make a few tests the results of which are here given.

Three samples of elixir digestivum compositum and a check solution of pepsin \( \frac{1}{30000} \) were used.

The first sample was made June 18, 1908.

The second sample was made September 1, 1909.

The third sample was made January 9, 1910.

The check solution was made April 20, 1910, or on the day the tests were made.

The Pharmacopoeial test for pepsin was used—sufficient elixir to represent one-thirtieth of a decigramme of pepsin added to one gramme of
coagulated egg albumen at a temperature of 125° F. for two and a half hours. Every sample came up to the requirements of the U. S. Pharmacopoeia, showing no signs of deterioration or loss of power to digest albumen.

Samples of these same elixirs were tried on fresh cow's milk for coagulating properties.

Fifteen drops of elixir added to four ounces of milk at 100° F. coagulated the milk in fifteen minutes. The pancreatin-check solution took twenty minutes.

On account of the alcohol, acids, and large amount of liquid the starch test was not attempted, nor were tests for diastase made.

As these elixirs were from three months to two years old and still retain their pepsin activity we believe the pepsin ingredient is as it should be.

The pancreatin tests were not carried out fully enough to make a positive statement regarding the activity of the pancreatin, but we believe it is active. Perhaps the diastase is entirely destroyed but some one having the ability and time should determine this as nothing in a theoretic line will satisfy the writer after making the above practical tests.

Physicians will continue to prescribe mixed enzyme liquid preparations especially if they are palatable and pharmacists will continue to dispense them.

If Elixir Digestivum Compositum is left out of our books of standards there will be a great variation in the color and strength of ingredients, and much injury will be done both to ethical medicine and pharmacy.

The writer has samples of various enzyme preparations from one to five years old with and without the addition of potassium iodide.

If there has been any change in the digestive properties of any of these it is only very slightly noticeable although there is a precipitate in every preparation with potassium iodide.

Every pharmacist knows that iodides and bromides are frequently prescribed with enzyme preparations, but it is seldom they see these solutions after making them up as they are nearly always dispensed immediately, otherwise he would notice a change in color in all of them with a precipitate, both occurring after twenty-four hours.

The colored elixirs become very much darker. The precipitate is probably inert albuminous matter.

PHARMACEUTICAL NOTES.

BY CHAS. H. WARE, BALTIMORE, MD.

I hope your section will discuss the following: I suppose every one has had trouble with the N. F. formula for Essence of Pepsin; after standing several months, it turns sour and ferments enough to almost blow a cork out of the dispensing bottle. I find the following more satisfactory:
Pepsin (1 to 6000) ........................................ 11.25 Gms.
Rennin .................................................. 16.5 "
Lactic Acid ............................................. 2.0 Cc.
Spt. Orange............................................... 10.0 "
Glycerin .................................................. 125.0 "
Alcohol .................................................. 50.0 "
Syrup .................................................... 65.0 "
Sherry Wine ............................................ 365.0 "
Purif. Talcum ........................................... 15. gms.
Water enough to make 1000.0 Cc.

There is some talk of leaving *Ammoniated Glycyrrhizin* out of the U. S. P. Is there any good reason why this preparation should not be used as a substitute for other preparations of licorice? I should like to have it discussed. It seems to me it ought to become popular. I have used it in place of Purified Ext. Licorice, in the following: see page 975 National Standard Dispensatory—*Mist. Glycyr. Comp.*

Paregoric ............................................. 1111 f. ozs.
Wine of Antimony ................................... 11 "
Spt. of Nitrous Ether ............................... 1 "

Mix and add

Ammoniated Glycyrrhizin ................................ 46 grains.
Water .................................................. 10 f. ozs.

Filter into a bottle containing, Mucilage, f. ozs. 111, and Sugar, av. ozs. 20. I have not used it in Co. Licorice Powder, but I have no doubt it will taste better than wood licorice, especially if more sugar is added to make up for the bulky lignine.

*Elixir Iron, Quinine and Strych. Phosphates U. S. P.*, has been criticized, because of precipitation. I have had some trouble with it when the various solutions are added hastily. I suggest that the alcoholic solution of the alkaloids be added to the phosphoric acid and aromatic elixir, and this mixture stand for twelve hours, before adding Sol. Acetate Ammon.

*Elixir* after using *Valeric Acid Salts* in small drug stores, is there any way of neutralizing the odor which hangs around the place much to the annoyance of our customers? I have found that open vessels of strong ammonia water set around the store about ten minutes before weighing out such salts as Quin. Valer., Zinc Valer. and Iron Valer., will neutralize the odor in two hours, but Valer. Ammon. will not deodorize, and so my Elixir Valerate Ammonia is made in the back yard, and my next-door neighbor thinks the odor permeates from the store through two brick walls, and a 4 foot alley, into her house; which recalls to mind a drummer in my store, full of whiskey, so that the odor lingered a long time: a young lady hap-
pened in and telephoned a young man a couple of miles away, after she hung up the receiver she confided in me that that young man must have been drinking because she could smell his breath through the telephone as he talked to her.

**LIQUOR SODII PHOSPHATIS COMPOSITUS.**

**BY W. H. GLOVER, PH. G., LAWRENCE, MASS.**

This convenient and useful preparation caused the writer no end of trouble when he first introduced it to physicians by crystallizing in the bottle. At first it was tried in mixture with tinctures but does not mix well, although liquids of low alcoholic strength mix nicely. As glycerin is an old but good friend in pharmacy, it was tried in this preparation with good results and makes a preparation that is quite permanent. The following is the method I use:

- Sodium phosphate ........................................ 1000 Gm.
- Sodium Nitrate ........................................ 40 Gm.
- Citric acid ................................................ 130 Gm.
- Glycerin q. s. ............................................ 1000 Cc.

Put solids in flask on water-bath till solution is formed, cool, add glycerin and filter. I think if more druggists would make this preparation and show it to their physicians and explain its advantages over similar preparations they will be more than pleased with results.

**RANDOM NOTES.**

**BY J. D. A. HARTZ & THOS. MCELHENIE.**

These jottings are offered by this self-appointed committee of two as a result of a little journey in Pharmacy in the hope that some items may interest the Committee on Revision.

*Syr. Hypophos. Co. U. S. P.*—When this syrup is kept for some weeks on the shelf at the ordinary temperature of the store a flocculent formation appears just under the surface. This will not occur if a weak solution of phenol $\frac{1}{10}$ of 1 per cent. is used instead of water for making the solution of alkaline hypophosphites. The taste is not perceptible and there is no possible objection, therapeutically, to the employment of 0.45 Cc. (about 7 minims) in 1000 Cc. of the syrup.

*Elixir Aromaticum.*—There is no real need for so much as 25 per cent. of alcohol is this preparation. Four some weeks past I have used the formula of Mr. R. R. Johnston of Bucyrus, Ohio, published in the Pharm. Era May 20 1909 p. 469, which contains 67\% per cent. of alcohol and answers every purpose of a simple elixir that I can think of quite as well as the present official elixir and for many prescriptions it will prove an advantage especially when intended for children.

*Tincture of Iodine.*—The addition of potassium iodide to this tincture is
chiefly to promote the solution of the iodine and render the solution more stable.

We propose that use be made of the fact that the solvent action of the iodide is increased in a dense solution. Also it is a fact that a small addition of glycerin obviates the tendency of the skin to become harsh and dry and sometimes to crack if the tincture is applied several times on the same spot. We therefore suggest to proceed as follows:

Into a 1000 Cc. bottle put 200 Cc. of alcohol and drop in the 70 Gm. of iodine and 50 Gm. of potassium iodide. Shake occasionally during several hours until dissolved. Add 50 Cc. of glycerin and alcohol q. s. to make 1000 Cc.

*Compound Tincture of Green Soap.*—In making Tinctura Saponis Viridis Co. N. F., diluted alcohol should be used to prevent crystallization of stearates. We believe that the Committee on Revision may well consider the economic side of the question of lessening the proportion of alcohol in many galenicals, such as tincture of iron, tincture of iodine, tinctura saponis viridis co., etc. The aggregate in 40,000 drug stores would be well worth saving.

*Calx Iodinata.*—In some quarters there is quite a call for this mechanical mixture of iodine and calcium hydroxide. No mention of it appears in the usual books of reference. We offer the following:

Iodine, 70 parts.
Slaked lime, dry, 930 parts.
Triturate well and keep in a sealed bottle.

*Compound Mixture of Glycyrrhiza.*—The addition of 5 Cc. ammonia water to 1000 Cc. mist. glycyrrh. co. will tend to fix the glycyrrhizin and neutralize any free acid in the mucilage and reduce the volume of sediment.

*Ointment of Phenol.*—We recommend a return to the formula for 1890 for ung. phenolis as to the base as there is less likelihood of finding uncombined drops of liquified phenol in the ointment made with yellow wax and benzoated lard than in the petrolatum. Many dispensers will continue to make this from the liquified—95 per cent. acid instead of the melted but undiluted crystals. To promote the latter and only correct practice we suggest the warming together in any convenient quantity and vessel of equal weights of pure phenol and benzoated lard and use this in double the quantity instead of pure phenol.

*Granulated Sugar.*—In some laboratory notes by Mr. Hartz—on page 968 of last Proceedings (1909) occurs a statement as to the superiority of coarse granulated sugar for the uses of pharmacy. This is amply supported by the brilliancy of the syrups in Mr. Hartz’s store and the colorless and odorless simple syrup.

We believe it would be quite feasible for the Committee on Revision to insert in the purity rubric under *Saccharum* a clause defining the granules to be such as will remain on a No. 20 sieve. In buying by 100
lb. bag or in barrels one can secure this coarse grade easily at about 10 cents advance per 100 lbs.

*Soft Soap.*—It is easier to procure cottonseed oil of good quality than linseed oil and no alcohol or heat is necessary to make a soap of the best grade. Whichever oil is used, proceed as follows in any quantity from 1 to 65 kilos. The process can be completed in one hour.

1. Cottonseed oil .................................. 76 parts.
2. Potass. hydroxide Greenbank .................................. 20 “
3. Water .................................................. 35 “

To No. 1 contained in an iron cauldron pour in a thin uniform stream a cold solution of No. 2 in No. 3 gently stirring until the last of the solution has been added when a honey-like emulsion will have resulted which if set aside in a slightly warm situation until the next morning will be saponified.

**DRUGS AND PREPARATIONS WHICH GO TO MAKE THE PRESCRIPTION.**

*BY R. H. NEEDHAM, PH. C.*

Much has been written and said concerning the increase in use of U. S. P. and N. F. preparations in prescription compounding, particularly during the past two years. The systematic campaign instituted by the druggists as an organization has yielded some results, but not anywhere near expectations. To declare that certain favorable results are obtained, requires little effort for utterance and about the same space of time to be dashed off on paper, but to actually take one’s valuable time and slowly and carefully go through prescription files, making tabulations, is altogether a different proposition and furnishes a task that is irksome and rather uninteresting and not at all enumerative. The writer has been considerably interested in reading reports as to progress resulting from the concerted effort made by both physicians and pharmacists to restore the prescription to its status of former years, and he freely confesses, that for some time he was very optimistic as to what was being done. Since getting down to bed-rock facts and figures he has rather concluded that the rosy outlook owed much of its halo to hopeful fancies on his part and that of others and to a lack of acquaintance with hard facts as they really exist to-day.

Lest anyone should get the idea that the information gleaned has been taken from a narrow field, let it be said that the work has been carried on and conducted with a hope and desire that favorable results might obtain, at the same time, all research being carried on with impartiality. That the field is located in the southwest is no great disadvantage, as will be proven. A city of 80,000 inhabitants, a medical center of the state, having both a medical and pharmacy school within her bounds, the physicians prescribing, being graduates of schools from all parts of the union, it would
seem that the prescriptions taken would be fairly representative. Further, let it be stated that no one physician's prescriptions were selected, but the files were perused without any selection as to whom they were written by. It was noted that some very few prescriptions showed the writers were well informed concerning modern Materia Medica, while others showed all the ear-marks of having been written by mossbacks, who may have seen better days, but were now in a state of retrogression. As to the style of manuscript and Latin, there were all kinds with here and there a prescription delightful to behold, showing that the writer was alert and thinking, though the majority indicated a very passive state of mind and thought, with a pernicious activity on the part of the writer's hand which rendered the writing typically illegible. First, one thousand selected prescriptions written during 1909 were canvassed with a view of obtaining an idea of what was being prescribed throughout the country. These prescriptions were collected from the files of dispensaries, hospitals and drug-stores located principally east of the Mississippi river, and were written by physicians who ordered U. S. P. drugs and preparations and directed the compounding with skill and understanding.

Not a single patent or proprietary preparation appeared among the number selected, although there were some few New and Non-official Remedies. Second, the prescriptions compared were taken at random from files of those written and filled during the months of January 1909 and 1910. The files of some drug-stores were canvassed for both years, while others were taken but once in order to secure more variety of prescriptions and to avoid camping on the trails of a few certain physicians.

As to the results, let the figures speak for themselves. Of the one thousand selected prescriptions, 57 per cent. were liquids, 34 per cent. were solids, while ointments and suppositories brought up the rear with 9 per cent., of these two, ointments being greatly in the lead. Of the galenicals used in filling these prescriptions, tinctures, fluidextracts and extracts, were compared all the way through. Considering the three classes as a whole, it was found that the percentage for tinctures was 55.5 per cent., extracts 38.5 per cent. and fluidextracts, least of all, 6 per cent. A very few N. F. preparations were ordered.

The second lot of 1909 prescriptions showed solids, 43 per cent., liquids, 54 per cent., ointments and suppositories, 3 per cent.

<table>
<thead>
<tr>
<th>Prescription Type</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tinctures used</td>
<td>110</td>
</tr>
<tr>
<td>Fluidextracts</td>
<td>34</td>
</tr>
<tr>
<td>Extracts</td>
<td>84</td>
</tr>
<tr>
<td>N. F. Preparations</td>
<td>89</td>
</tr>
<tr>
<td>N. N. R.</td>
<td>172</td>
</tr>
<tr>
<td>Patents and proprietaries</td>
<td>343</td>
</tr>
</tbody>
</table>

Counting all N. F. preparations and comparing, exclusive of N. N. R., the percentages read, approximately:
DRUGS AND PREPARATIONS TO MAKE THE PRESCRIPTION.

Tinctures .................................................. 34 per cent.
Fluidextracts ............................................... 11 “
Extracts ..................................................... 27 “
N. F. ........................................................... 28 “

\[
\text{Total} = 100
\]

Note that New and Non-official remedies total 172 and acetyl-salicylic acid under its usual trade name, occurs 76 times or its percentage compared with other N. N. R. would be 44 per cent. or nearly \( \frac{1}{2} \) of this class of drugs was limited to this one article. The 1910 lot of prescriptions shows little change in some respects, in others marked differences will be seen.

- Tinctures used .................................................. 127
- Fluidextracts .................................................. 73
- Extracts ...................................................... 68
- N. F. preparations ........................................... 85
- N. N. R. ......................................................... 228
- Patents and proprietaries .................................. 291

Repeating the comparison as in case of the 1909 prescriptions, the approximate percentages are:

- Tinctures ...................................................... 37 per cent.
- Fluidextracts .................................................. 21 “
- Extracts ....................................................... 17 “
- N. F. .......................................................... 25 “

Attention is called to the increase in the number of N. N. R. and of this number acetyl-salicylic acid entered into prescriptions 110 times; about 48 per cent. or \( \frac{1}{2} \) of these new remedies prescribed were of this drug.

Let us count gains and losses during the year. 1910 shows the following approximate gains over 1909.

- Tinctures ...................................................... 15 per cent.
- Fluidextracts .................................................. 115 “
- N. N. R. ......................................................... 32 “

The losses for 1910 over 1909 were of three classes, all quite important.

- Extracts ....................................................... 45 per cent.
- N. F. .......................................................... 4.5 “
- Patents and Proprietaries .................................. 18 “

The other ingredients used in the prescriptions consisted largely of organic and inorganic salts following the the usual routine; if soluble or deliquescent, being ordered dispensed in solutions; if soluble and more permanent, in papers or capsules. The facts to be demonstrated in this article are, that the preparations upon which so much care and time is spent both by the Pharmacopoeia and the theoretical and laboratory teaching of pharmacy,
are sadly neglected by the physicians. While true, that fluidextracts show a handsome gain, observe the meager use during the first year. After looking the data over, one is tempted to inquire what is the actual use or benefit to be gained by the valuable time given to prescribing methods of manufacture, assay processes, etc., when not over ten different tinctures seem to be demanded in the average drugstore and of the fluidextracts ordered not a few are unofficial. The major part of the tinctures, fluidextracts and extracts are to remain on our shelves drawing dust and dirt, but no interest on capital invested.

One very remarkable fact is not shown in this investigation, though the apparent gain in N. N. R. is considerable and the use of acetyl-salicylic acid is rapidly increasing in favor with physicians, yet inquiry brings the reply that the number of prescriptions in which this drug enters is a poor index as to its use by the laity in self-medication. Reports bring the startling information that it is becoming a staple, supplanting acetanilide and other coal-tar products.

The propaganda for reform has an immense amount of work yet to do, for though patents and proprietaries show a decrease in prescriptions, yet the startling figure for the first year is almost three times as great as that of tinctures. Physicians approached on this subject reply that when the Pharmacopoeia contains those preparations which give the results they desire, then will they cease to prescribe patents. In other words, shall the U. S. P. become a patent-medicine almanac and all the labor of decades go for naught? The drugs which go into many of these ready-made prescriptions are enumerated in the Pharmacopoeia, and no one acquainted with the Pharmacopoeia would ever suggest such a backward step. Let the U. S. P. remain a book of standards and simples, the National Formulary and dispensatories will still be able to take care of the other preparations. Too many of the pharmacists are drifting with the tide, being carried with the current, caring little as to what enters into the prescription. While they are sleeping commercial men, not the revisors of the Pharmacopoeia nor prescribing physicians, are directing and dictating as to what shall enter into the prescription.

THE PRACTICAL SIDE OF A PROFESSIONAL PHARMACY.

BY J. LEON LASKOFF.

A great deal has been said at pharmaceutical meetings and pharmaceutical periodicals are full of literature concerning the elevation of pharmacy as a profession, all tending to raise the standard of the profession on a par with others. However, all or at least the greater part, has seemed to me to be "problematical" or I may say "speculative" and only because the remedy suggested was of such nature that it would almost be impossible (under these existing conditions) and in very many instances too ideal.
My personal experience in foreign countries and in this country has taught me that there is a royal road to the success of the modern Pharmacy as a profession, if members bear in mind some or all the factors, which I have attempted to outline for their consideration and approval. In every civilized country of this world, other than our own progressive America, Pharmacy as a tone profession they make a distinction between the mercantile druggist and the professional pharmacist. This fact I have pointed out before in another article. However, custom has decreed that we to-day are encumbered, because we combine our efforts in the direction of one "goal," namely to make "money," and practicing our art in a "store."

Now, inasmuch as we must do so in order to live up to custom, and incidentally to the expense incurred in conducting our business, this remedy—and I may say it with a marked degree of positiveness—lies in the "divorcing" or separating our store from our dispensing department, not merely by putting up a counter partition, or ground-glass partition, but by having an entirely separate and distinct room in which there shall be not only the necessary paraphernalia, such as scales, graduates, mortars, spatulas, etc., but a full line of the necessaries in use every day, for compounding drugs, chemicals, tinctures, syrups, etc.

The store should be divided in such a way that the prescription department would occupy the major part and the front of the store should be used only for mercantile purposes, containing the soda fountain, sundries, proprietarys, etc. The prescription department should be an entirely separate feature and by itself, where strict silence and secrecy can be observed. Proper checking-off of the doctor's prescription avoids errors and "complaints" and where we can properly fulfill the extreme responsibility thrust upon us, and safeguard ourselves against erroneous dispensing. Remember that human life is at stake, and accuracy is our salvation. Prescriptions should never be dispensed in such a way that the laity can see it done. If a customer sees you measure off a liquid in a graduate he may feel nervous to think that perhaps you may make an error and give him one drop too much, and poison him, his wife or his children. Employ competent help. They will cost a little more, but are cheaper in the end.

Now, a word as to some of the "stumbling blocks" that we meet in our practice. Now and then a "sticker" shows up in the way of a peculiar mixture, pill, capsule or ointment prescribed by the doctors, which if not properly put up will not be desirable. Either they will be bad-looking, too bulky, not uniform or as in ointments gritty, lumpy, etc.; and yet you have followed the order and used all the correct ingredients. There is a great deal of tact to be used in some of these cases, and we should never consider a little waste of material, if it is necessary for us to bring about a good result, to discard a poorly made prescription and experiment in var-
ious ways to attain the desired result. Neatness in the general appearance of our ointment, capsule or mixture counts for a good deal and all help to build up your general reputation and incidentally your trade. To gain the confidence of the physician, never let it be said by your brother pharmacist that he can make up a certain “prescription” which you have already dispensed and sold better than you.

I could illustrate hundreds of prescriptions which came to my notice, but the following will suffice to show you what is meant by using care and a little trouble, with but very little expense:

(1) Codeine ........................................ 0.6
    Compound Tincture Benzoin .......................... 30.0
    Syrup ........................................... 90.0
    Water ........................................... ad 120.00
    MDS as directed.

By dispensing this prescription in the way it is written the benzoin will separate and stick to the bottom of the bottle, but by adding one drachm of powdered acacia the mixture will be uniform and elegant in appearance.

(2) Sodium Bromide .................................. 4.0
    Calcined Magnesia ................................ 0.8
    Validol ......................................... 4.00
    M. Div. in capsules No. XII.

To put this up in capsule form, the way it is written, is absolutely impossible, except a mess is made and then the capsules will be of an enormous size, but by adding 10 grains more magnesia it will form a nice dry powder, and you can dispense it in No. 1 dry capsules, which will look white and elegant in appearance.

(3) Ol. Theobrom ................................... 12.0
    Ol. Amygd. dulc .................................. 15.00
    Sulphur Ppt ...................................... 3.0
    Resorcin ....................................... 1.5
    Ol. Rosæ ........................................ gtt. 4

The best way to dispense this prescription is to melt the ol. theobrom. and the almond oil; then dissolve the resorcin in a few drops of water and rub it up thoroughly with the ppt. sulphur; then rub the rest of the ingredients on a slab little by little with the melted cacao butter, until it forms a nice smooth, perfect ointment.

(4) Bals. Peru ....................................... 
    Ungt. Zinci oxidi aa ............................ 15.0
    Mf. ointment ....................................

This prescription looks very simple, but you will be surprised when you
rub the two ingredients together, it will form a gritty hard ointment which is absolutely impossible to apply on any sore. After long experience I found that a few grains of powdered acacia added to the Peru balsam and mixing same with the zinc ointment, the mixture will form a nice smooth soft ointment.

The above-mentioned prescriptions were dispensed in different stores in different ways, but I think after a little experimenting I have succeeded in doing them up in the most satisfactory way. Now, a little code of "Ethics," which it does no harm and always does good to observe.

1. Always show a friendly and professional spirit to all physicians with whom you come in contract.
2. Always treat your competitor fairly and squarely.
3. Never criticise a prescription to the patient.
4. Never discuss the relative merits of the physician in his prescription with your customer even when he asks you to do so.
5. Never make a diagnosis—always leave that to one who knows—the doctor.
7. Never practice medicine or surgery.

The above may serve us all as the decalogue of pharmacy. To elevate the profession some good rules are worth while mentioning of great importance to the professional pharmacist.

1. Never have any kind of window display other than that which relates to your own profession. Do not specialize with patents or unethical nostrums.
2. Use neat bottles, boxes and labels. Make neat packages.
3. Write labels plainly and distinctly, and in full as per "signature," not abbreviated.
4. Make note of size and weight of masses in pills and capsules on prescriptions, so that repetition will correspond with the original dispensing.
5. Always keep the latest ethical remedies in stock and request the manufacturer to send notice to doctors that you have done so. This is good advertising; it is strictly ethical, and at the same time scientific.
6. Buy only the best drugs and chemicals from reputable houses. The physicians will obtain the desired result. Any preparation you yourself manufacture should always comply with the standard of U. S. P. and N. F. (N. B., our "Holy Bible.")

Complying with all of the above-mentioned rules, physicians and the public in general will have more confidence in you. This may not all appeal to all of our members, but a little reflection on their part may awaken
them to a realization of the vast importance of this feature. Many I know will say, "What's the use? We have been able to get along so many years in the old way; why change it now?" And now, gentlemen, there lies the danger. The warning note has been sounded; competition with the cut-rate stores is now so keen that we must find a remedy. Let them thrive on cut-rate prices and miscellaneous goods. You cannot do it. Let them spend money on advertising and displays; you cannot do it. Let them have candy and other side-lines; you cannot do it. Let them carry an enormous stock of everything for the household; you cannot do it. But they can't prove themselves truly and honestly professional pharmacists, and what is more, you can.

You are in direct contact with the doctors and patients. You are right in their midst. You can show them that you can dispense the prescriptions; you can gain their confidence as to your ability and accuracy; you can show them that you are a pharmacist and not a merchant, pure and simple. They will then bring their prescriptions to you; they will buy what they need from you, and you will incidentally reap the harvest that is due you. That is why you should make a "specialty" of your store; that is why you should practice a "specialty" as is done in other professions. Become a prescription specialist. Make your store look like a professional store, not a dry-goods store, candy shop or patent-medicine cut-rate establishment.

We pharmacists have been awakened from long sleep and must be up and doing. Remember the story of the lion and the mouse. We must endeavor to put a net around the lion and then we can feel safe. We have taken the wrong steps to endeavor to compete with those who are trying to devour us. We imitate their methods. We try to do as they do. Gentleman, we cannot, and if we do, we are signing our own death warrant. We have neither the capital nor the facilities to do it, but we have the brains, the knowledge to elevate ourselves far above the standard of of the big stores to-day, by making our only "specialty" (and you know it is a paying one) dispensing; you will sell all other things just as you have heretofore, and if you should sell a few bottles less of some proprietary preparation which are on our shelves and in our closets, you may be able to save a few dollars.

Much more could be said and written upon this very valuable subject, but inasmuch as there is nothing new to which I lay claim, yet a strict observation of what has been written will go a long way in paving the rocky road to a successful issue, to which we are trying to attain. Let the blue laws of our profession be revised. Let us be awake and looking for the future. In fact the future is now very near, and we must be ready to face it—not as merchants but as professional men.
"QUALITY VERSUS QUANTITY OF U. S. P. AND N. F. PREPARATIONS."

BY ABRAHAM WEINSTEIN, N. Y. CITY.

I believe that the usual way of doing our duty to pharmacy by annually presenting papers to the convention so as to help to increase the pages of our U. S. P. and N. F. is out of date, and not in accord with the progress of our present day, because, in my opinion "quantitative pharmacy" has already reached its summit and it is high time now to look down upon the road it has traveled and examine whether it was really for the welfare of humanity and pharmacy to pile up such huge quantity of preparations for public use and pharmaceutical interest.

Not how much but how well should be the golden rule in pharmacy and my earnest hope is that the next revision committee will direct their efforts solely to improve the already too many complicated preparations which crowd the pages of our official books.

It is the spirit and not the letter which moves the world: every formula inserted in our official books should be infused with the spirit—first, how best to serve the sick of our country, second, the welfare of the medical profession, their interest must be kept up in pharmacy as a science and art, and in this day of struggle must agree with the time and patience they can devote to its interest.

Simplicity and improvement should be the scope of the revision committee in the future.

MISTURÆ CONTRA DIARRHÆAM—DIARRHÆA MIXTURES.

These preparations are never or very seldom now prescribed by physicians but too often called for by the public due in many cases to the enormous amount of opium they contain. It is therefore time that they should either be discarded altogether or the opium replaced by some other innocent ingredient. It will certainly not offend the distinguished originators of the formulas if we can thereby save at least one life from the terrible misery of a fiendish habit.

ELIXIR DIGESTIVUM COMPOSITUM.

As a digestive elixir it ought to contain more pancreatin and diastase, and no pepsin at all. Pepsin is not the best digestive ferment we have; pancreatin is richer in ferments containing trypsin, amylopsin, and steapsin. I believe the following improvement should be made:

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pancreatin</td>
<td>20 Gm.</td>
</tr>
<tr>
<td>Diastase</td>
<td>10 Gm.</td>
</tr>
<tr>
<td>Sodium bicarbonate</td>
<td>20 Gm.</td>
</tr>
<tr>
<td>Glycerin</td>
<td>250 Gm.</td>
</tr>
<tr>
<td>Water</td>
<td>125 Gm.</td>
</tr>
<tr>
<td>Tr. cudbear</td>
<td>15 Gm.</td>
</tr>
<tr>
<td>Purified talc</td>
<td>15 Gm.</td>
</tr>
<tr>
<td>Aromatic elixir</td>
<td>1000 Cc.</td>
</tr>
</tbody>
</table>

As a diagnostic elixir it ought to contain more pancreatin and diastase, and no pepsin at all. Pepsin is not the best digestive ferment we have; pancreatin is richer in ferments containing trypsin, amylopsin, and steapsin. I believe the following improvement should be made:
Introduce the powders in a mortar and rub with water until solution is effected; add the other ingredients; incorporate the talcum with the mixture and filter. It is with malice toward none and love of improvement for the benefit of all, that I was animinated to offer these suggestions. Let me hope that it will meet with the approval of those whose welfare I seek.

SPIRITUS MENTHÆ PIPERITÆ.

The direction of macerating the oil together with the leaves in alcohol for 24 hours is not practical, for the leaves unnecessarily absorb some of the oil. The better way is to macerate the leaves with the alcohol for 24 hours, filtering and then adding the oil.

TINCTURA IODI.

The popularity of this preparation with the public demands that it should be reduced to ½ the present strength. I am positive that every practicising pharmacist will recall more than one case of a burn with the tincture. So frequently are the complaints in my store, that I am compelled to keep the official "Glyceritum Amyli" and carron oil near the iodine tincture. The strength of the British Pharmacopœia which is about ½ the strength of our official tincture and prepared by the same method would prevent such disagreeable occurrences.

ELIXIR PEPSINI.

This preparation ought to be discarded from the N. F. altogether and "Essentia Pepsini," which is the better preparation, be recognized only. There is absolutely no reason why an inferior preparation should be retained when a superior one is introduced. The physician wants the best preparation obtainable and does not care about the name.

UNGUENTUM PHENOLIS.

The present official ointment is a faulty one because the carbolic acid which is not soluble in petrolatum is thrown out of the incorporation in a very short time and the result is either a dangerous one of getting too much carbolic acid or a worthless one containing none of the phenol. The old formula of using ointment should be restored as the carbolic acid is completely soluble in fats and makes a permanent uniform ointment.

EMULSUM OLEI MORRHÆÆ.

This preparation has been the cause of much trouble and to some loss of reputation and money. I know personally of many explosions it has caused, due to the presence of sugar in the form of syrup with acacia which is composed chiefly of arabic acid. While sugar is not directly fermentable it is easily converted into dextrose and levulose under the influence of dilute acids or micro-organisms, and is then fermentable. The remedy seems to be to abandon acacia and use a different emulsifying
agent. The chondrus emulsion of the N. F. or a tragacanth emulsion is more stable and satisfactory. The substitution of glycerin will not do in this preparation as glycerin spoils the emulsion by precipitating the acacia.

Quality absolute and pure is the demand of the day; for the light of reason is penetrating our country everywhere in our national "House," Senate, press, and behind the counters of the mortar and pestle men.

The following preparations are a few of the many which can be simplified and improved.

"Elixir Ferri Quininae et Strychninae Phosphatum." This preparation seems so complicated and confusing to the ordinary pharmacist that he has been forced to give up manufacturing it for the "ready made specialty." The purpose of this formula is a preparation containing in each teaspoonful 3/4 grain quinine, 1/4 grain strychnine, in the form of phosphates, and one grain soluble phosphate of iron, in aromatic elixir, which seems very simple yet a whole page of the U. S. P. is taken up with the ingredients and methods of preparation. The addition of ammonium carbonate, acetic acid, and ammonia water to form ammonium acetate, is not at all necessary for it does not at all prevent the annoying discoloration which is due to the saccharine solution of the elixir in the presence of some free phosphoric and acetic acids. A much better preparation is obtained by simply reducing the wise official preparation "Glyceritum Ferri Quininae et Strychninae Phosphatum" to the specified elixir strength, with an aromatic elixir made with glycerin instead of sugar, the stability and color of which is thereby assured or by using the same ingredients and method accordingly as directed in making the glycerite of the I. U. S. P.

CRITICISMS OF THE TINCTURES OF THE UNITED STATES PHARMACOPEIA.

BY PAUL J. WALDNER, PHARMACIST, U. S. NAVY.

The fact that a paper of this title has been invited gives evidence of a general belief that this class of preparations stands in need of more or less revision. Briefly, the criticisms which apply to the tinctures official in the eighth revision of the Pharmacopoeia may be summed up as follows: (a) That a certain number now official should have no place in the Pharmacopoeia; (b) that the class embraces several preparations, notably tincture of iodine and camphorated tincture of opium, which are not tinctures in the accepted sense; (c) that there is still much to be desired as regards uniformity in percentage composition; (d) that no standards of potency are established in several important instances; (e) that some provision should be made whereby duplication of tincture and fluidextract may be honorably avoided in cases where the menstruum is the same.

In this paper individual tinctures will not be discussed. Thus considered, the class presents a broad field for pharmaceutical and physiological
experimentation and constitutes a task which no single individual should, or properly can, undertake. Considered entirely as a class, and disregar-ding specific drugs or their tinctures, this group of pharmaceutical galenicals offers a profitable subject for discussion. This applies with even stronger emphasis to the sister class, the fluidextracts, a class of preparations whose virtues and excuse for existence are debatable when considered in the light of their present limited field of legitimate usefulness, and the sins, therapeutic and pharmaceutical, which they have occasioned. It seems pertinent to interject these remarks in view of the bearing which this class of preparations has on the tinctures as often dispensed, and the too frequent and disreputable intimacy which is often permitted to exist between them. Saving the presence of the manufacturers, fluidextracts may safely be said to constitute one of the big nails in the coffin of ethical pharmacy—although not a few of them have proven good and useful preparations.

Beginning with (a) under the general criticism, we are confronted with the ever-perplexing question as to which preparations should be dropped. With the passing of empirical medicine and the growing movement for a scientific administration of drugs, we find the armamentaria of physicians becoming more and more uniform and relatively restricted. The Pharmacopoeia, to serve its best purpose, should as nearly as practicable anticipate future requirements, rather than reflect only the experiences of the past. With this object in mind it will be found that much more or less obsolete material can be justifiably dropped. Recognition of this feature will, however, entail the exercise of a liberal and broadminded discretion on the part of those seasoned practitioners who have a voice in revision. Those tinctures which may be eliminated, need not however be entirely denied recognition. The writer would propose that provision be made in the forthcoming Pharmacopoeia whereby the standard of such tinctures as are eliminated may be fixed as that which obtained in the Pharmacopoeia in which they were official. This plan could possibly be made to apply similarly to other classes of preparations. The objection which might be advanced against this scheme is that it would entail familiarity with former Pharmacopoeias on the part of both physician and pharmacist, but this contention loses force when it is pointed out that the physician who prescribes such preparations is presumably familiar with them, and the hardship on the druggist would be wholesale. In the discussion of the relationship between tinctures and fluidextracts, a list is given of those tinctures which are suggested for elimination.

(b) While tincture of ferric chloride and camphorated tincture of opium are tinctures within the strict definition, they are hardly so in the accepted sense of the word, and the latter particularly must always stand out as a distinct exception in any plan involving a desire to make for uniformity of percentage strength of principal ingredient. Considering iodine and ferric chloride together, they represent the only tinctures which are
solutions of inorganic drugs. If radical changes are to be made in the Pharmacopoeias, it might be well to consider the advisability of redistributing these preparations under other classes, or to combine the anomalies of all classes of preparations into a separate class.

(c) Regarding uniformity in percentage strength much has been said and written. A decided forward step in this direction was made in the last revision and those who predicted disastrous consequences as a result of the more radical changes have not been supported by the developments.

It would seem a most propitious time to adopt a rule of one-strength tinctures, now that so much progress has been made toward this end. The idea, advanced by some, of having the tinctures of such strengths that all could be given in a like dose, is not based on sound clinical experience. This plan would give rise to tinctures of widely varying strengths, and the variations in potency represented by the different drugs would involve either extreme concentration in certain instances, if a small dose were fixed upon, or, on the other hand, such dilution in other cases as would forbid the use of given tinctures in disease conditions where alcohol is distinctly contra-indicated. Moreover, intelligent dose adjustment to the individual case presupposes a clear understanding of the quantity of drug represented, which would be no difficult matter if all were of one strength, but would be even more perplexing than it is now if the plan outlined were in effect.

(d) Standardization.

The work of Sharp, Rippetoe, Hamilton, Houghton and others with certain drugs, such as squill, strophanthus, digitalis and ergot, shows that these drugs need no longer be administered haphazardly and that standards of potency, deduced from experiments which have brought results which could be accurately recorded, may reasonably be expected. The contention that such processes, in distinction from the assays, cannot be carried out by the dispensing pharmacist should have no weight in deciding the question. Reliance, on the part of physicians, on the physiological action of these drugs is so amply justified by clinical experience, that the therapeutic activity of their preparations should not be left to chance or the good intentions of the pharmacist.

(e) The relation of tinctures to fluidextracts, and list of tinctures suggested for elimination. No law is so useless as that which is extremely onerous or difficult of enforcement, and that ethical, unwritten law which forbids the dilution of fluidextracts for the preparation of a tincture is a striking example. Knowing, as we all must, that the rarely used, as well as some very popular tinctures, are in many instances made by dilution of a fluidextract, it might be just as well to recognize the hard fact and, wherever it can properly and consistently be done, legalize a method whereby dilutions—either of fluidextracts or, possibly, of such fluidglycerates as have been proposed by Beringer—may be dispensed as tinctures.
This plan would make the proceeding proper in the cases for which it is prescribed and, by inference, wrong in every other instance. The list below embraces those tinctures which have a corresponding fluidextract made with a menstruum like that prescribed for the same tincture, or with but a negligible difference. Digitalis has purposely been omitted because it is believed that this preparation should be physiologically standardized. Lobelia, sanguinaria and squill have also been omitted for the reason that the fluidextracts of these drugs are acetic acid extractions while, with the exception of sanguinaria, the tinctures are made with an entirely hydro-alcoholic menstruum.

List of tinctures which have corresponding fluidextracts made with practically similar menstrua; those in italics are recommended for elimination and for those in plain type a dilution of the fluidextract is proposed as the official tincture:

<table>
<thead>
<tr>
<th>Aconite,</th>
<th>Hyoscyamus,</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bitter orange peel</td>
<td>Krameria,</td>
</tr>
<tr>
<td>Capsicum,</td>
<td>Quassia,</td>
</tr>
<tr>
<td>Cimicifuga,</td>
<td>Quillaja,</td>
</tr>
<tr>
<td>Colchicum seed,</td>
<td>Serpentaria,</td>
</tr>
<tr>
<td>Cinchona,</td>
<td>Stramonium,</td>
</tr>
<tr>
<td>Indian cannabis,</td>
<td>Valerian,</td>
</tr>
<tr>
<td>Calumba,</td>
<td>Veratrum,</td>
</tr>
<tr>
<td>Gelsemium,</td>
<td>Ginger.</td>
</tr>
<tr>
<td>Hydrastis,</td>
<td></td>
</tr>
</tbody>
</table>

List of tinctures recommended for elimination; those in italics are included in the above list and their drugs have now an official fluidextract:

<table>
<thead>
<tr>
<th>Aloes,</th>
<th>Hydrastis,</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aloes and Myrrh,</td>
<td>Pyrethrum,</td>
</tr>
<tr>
<td>Arnica,</td>
<td>Quassia,</td>

<td>Tolu,</td>
</tr>
<tr>
<td>Calumba,</td>
<td>Valerian.</td>
</tr>
<tr>
<td>Cinnamon,</td>
<td></td>
</tr>
</tbody>
</table>

It is proposed that for such tinctures as are eliminated, the standard be established which was prescribed by the Pharmacopoeia in which they were official. The modifications herein proposed would obviously necessitate some readjustments in other directions in conformity with the changes affected, but these are minor details not difficult of solution.

In conclusion, it should be borne in mind that at the present time one of the cardinal aims should be the development of confidence in, respect for, and particularly employment of, the official preparations on the part of physicians. The use of tinctures is dependent upon the physician’s familiarity
with them. Simplification, wherever practicable, should be the keynote, so that the medical fraternity will look to the Pharmacopœia rather than to the "hand-me-downs" of the manufacturer. Furthermore it should be remembered that these preparations are, or should be, largely made and must be kept on hand by the retail pharmacist whose time and material must be economically expended to meet the active competition of the day.

THE DISPENSER.

J. WINCHELL FORBES, ROSSMOYNE, O.

I have a very large correspondence, and I often get letters which set me to thinking, but I haven't received one in a dog's age, which made me pull my thinking-cap as far down as one from Otto Raubenheimer, chairman of the Committee on Practical Pharmacy and Dispensing.

Raubenheimer says: "As one of the few who are able, and who are willing to criticise the U. S. P. and National Formulary, I hope you will contribute a paper to my Section."

So far as the willingness is concerned, he may be right, but as regards the ability; it strikes me that it must be pretty poor specimen of a dispensing pharmacist who is not competent to form some kind of an opinion as to the merits or defects of his standard text-books, especially under present conditions.

My active work behind the dispensing counter ceased in 1874, that is, more than thirty years ago, and since that time, there have been wonderful changes in both the business of pharmacy and its status as a profession. In those days, the Pharmacopœia, although nominally the text-book of the "back room," was in reality a work which was of infrequent presence in the drug store, while the National Formulary was in a tentative stage, as a collection of formulas which "those Brooklyn fellows" had found to be satisfactory in their neighborhood. The United States Dispensatory was the pharmacopœia. It was not looked upon as a commentary, but as the real fountain-head of all pharmaceutical wisdom and knowledge. "It isn't in the Dispensatory," settled it. If some fool doctor asked a pharmacist if he had a copy of the U. S. Pharmacopœia, he was handed the Dispensatory, and that might be the U. S. or the Standard, for very few had a copy of both.

Of course, I refer to condition, on the Pacific Coasts; but I am of the opinion that it was about the same in "The States," for our experience with late arrivals from the other side of the Rockies, was that the demands were lighter on pharmacists in their home cities than with us. The reason is not far to seek. Owing to the unusually cosmopolitan character of our population, we were compelled to supplement our U. S. and Standard Dispensatories with the French Codex, Dorvault's L'Officine, and the Pharmacopœia Borussica, the British, Edinburgh, and Dublin dispensa-
tories being taken care of by the United States Dispensatory. This was peculiarly the case as regards San Francisco, but as prescriptions often wandered off into the country sections, where the extra works were unknown, Wakelee, Thayer, Lefevre and Rotourier, in San Francisco received many prescriptions for filling, from the benighted sections.

Even Sacramento, the next largest place to San Francisco, was one of those sections as Jim Doherty's was the only place in the city where prescriptions not founded in the dispensatories stood the least chance of being understood and correctly filled. I was with Doherty for four years, and I know that at that time he had the only copy of the U. S. Pharmacopoeia in town, besides my own private one.

There might have been other pharmaceutical journals published in this country, but at that time (during the early sixties) the only one that I knew of, was the American Journal of Pharmacy. Doherty was a subscriber for this, and also for the British Pharmaceutical Journal, and these two kept us pretty well posted as to what was going on in professional pharmacy. The era of so-called commercial pharmacy had not yet begun, and that of cut prices for drugs and proprietaries was yet in the womb of the Future.

As I contemplate the conditions of to-day, I may well pull my thinking cap well down over my ears, before beginning a paper dealing with dispensing pharmacy, especially with regard to a work which deals largely with a lost art for the average retail druggist who buys his galenicals ready-made, and as I have known to be the case, even to peppermint water, lime water, etc., and who rolls his pills out of a bottle, instead of on a pill machine.

The only man who is able to write such a paper is manifestly the "man behind the gun," the one who wrestles with modern conditions. The men behind the guns have of their own accord surrendered the professional part of the business to others; hence they have surrendered the Pharmacopoeia with it, and to those others must fall all criticism or commendation of that work. As regards the counter manipulation of the very present, it seems to be reduced to the preparation of extemporaneous prescriptions, and with the advent of the modern synthetics, and their extensive use by the doctors, it would appear that in this direction, dispensing practice is reduced to determining incompatibilities which cannot be predicted from chemical considerations, but which we only find when we run up against them in actual practice, and here again we find that we must depend upon the men behind the guns.

However, experience has taught me that Experience is not a thing of the future, but one of the past, and thirty-odd years of active work behind the dispensing counter has shown me that even with our present army of journals, and their contributors, knowledge is slowly assimilated by pharmacists, and that even the best of us habitually pass by many things of
value. Every day it comes home to me what opportunities many are passing by by not allying themselves with the American Pharmaceutical Association and their local societies, and subscribing to pharmaceutical journals, the more the better.

There has been much agitation in regard to the principle of cooperation as a means of bettering the present condition of the pharmacist. One of our local papers, only a short time ago, had an editorial calling attention to the fact that no cooperative plan had ever succeeded which was not founded upon some form of religion. The nominal basis of the most successful organization of pharmacists, the N. A. R. D. was the religion of "Live and let live;" its efforts are now largely founded upon another, "honest goods and honest service," and to be sure of the honest service, the educational bodies are insisting upon a high mental status and better education for those who are to take the places of the present generation of pharmacists.

This is what the dispenser of to-day is facing, and it behooves him to add continually to his knowledge, in every possible way, or when he comes to the time of the sere and yellow leaf, he will find that young blood has displaced him at the counter, for he will not have the experience and knowledge to offset the youth of his competitor.

Now this is more of a paper on the dispenser than one on dispensing, but let those who are beginning the race, heed the words of one who has been, and is a careful student of the conditions of pharmacy, both the old and the new. The time is coming when there will be a sharp division between professional and purely commercial pharmacy.

It will not be to-day, it may not be to-morrow, but the separation will be surely made, and it behooves those who elect to follow a profession to set themselves apart from those who devote themselves to the ideas and methods of trade.

One is as honorable as the other, but the routes to the goal are different, and few can win success in more than one line of endeavor, and as the line of dispensing is on the professional route, those who elect to follow that route must qualify and keep qualifying themselves, as they travel it, if they hope to reach the goal.
MINUTES
OF THE
SECTION ON HISTORICAL PHARMACY.

SATURDAY MORNING, MAY 7, 1910.

The Section on Historical Pharmacy was called to order at 10:15 a.m. by Chairman Eugene G. Eberle, of Texas, who proceeded to read his address as Chairman as follows:

CHAIRMAN’S ADDRESS.

The address of the Chairman of the Historical Section is usually considered perfunctory duty but you will admit of a few suggestions which he thinks will perhaps be of some value to the Association. Some, and perhaps most of the ideas have been pronounced in the work this Section has been doing. Biographical sketches of men prominent in pharmacy have been collected together with letters, writings, etc. This should continue a purpose of this Section, and should be of more direct interest to those who have lived in the same community with the deceased; the contributor should add his comment on the useful life that has passed out. In this connection the additional suggestion is made that men who are prominent to-day in the various branches of pharmaceutical work, write their autobiographies. These need not be read if so requested, nor is it essential that they be presented, but let the contribution be available at a designated time for use of the Association.

Again, histories of associations, boards of pharmacy, schools of pharmacy, etc., are written most accurately while those are still living who have played a part. It has therefore been the endeavor of the Chairman to arouse an interest of this kind, resulting possibly with some degree of success, for in recent years such historical data have appeared in a number of State Proceedings. The same suggestion applies to drugs and preparations; every year finds its quota. Comparatively few remain with us while some that are discarded attract attention in later years with little available authentic reference. This of course only applies to those of local use, for more extended application brings these to the consideration of associations and the press.

Since first writing this report, that of the Historian has come to hand and includes perhaps what were in the mind of the writer the more important items to be noted, and as these are better stated by him, they have been eliminated from the Chairman’s report, except this immediate reference. It is a most difficult matter to arouse interest for this Section. To what in particular this indifference is due, we can not say but it may be the impossibility of publishing more than the simple notice that such contribution was received.

It is unnecessary to refer to the need of authentic historical data; perhaps their
greatest value, the writer discerns in the analysis of future possibilities and conditions, for development and progress are not by straight lines. We should have a true conception of the past, not only the glitter, but as Tennyson states it, the frosty dark, and reversely, those who only see the beclouded past should be able to recognize the glimmer. We may see before us a brighter future, while others are extremely doubtful, and withal we should realize that there is a deliverance from every unfavorable condition, not only of our lives but our profession, when we have fitted ourselves to accept it. History is a good reference and compend and therein, aside from other interest, is its value.

The work of the Chairman has not been arduous; he has written many letters requesting contributions, with some responses that are presented by the program of the Section. He will not call attention to any of these in particular, except to say that the historical sketch of the Idaho Pharmaceutical Association came to him after the meeting at Los Angeles, and the sketches of the Presidents of the Arkansas Association have appeared in print. The writer has in hand further contributions on early pharmacy in Texas, but not sufficiently complete for presentation.

Secretary Dunn called for action upon the Address just read, and Mr. Motter, seconded by Mr. Hancock, moved to receive and refer for publication. So ordered.

The Chairman called for the report of the Historian as next in order, and Mr. Kremers made his report as follows:

REPORT OF HISTORIAN.

The work of the Historian during the past twelve months has taken its usual course: the collection of new material, and the classification of material already in hand so that it can be properly stored and used.

In the collection of material two members of the Association have continued to take a special interest. Mr. Mayo has sent a number of photographs and Mr. Whelpley has sent miscellaneous documents as well as forwarded several boxes of documents collected by Ex-Treasurer S. A. D. Sheppard.

In the work of arranging material on hand, your Historian has been ably seconded by Miss Nellie Wakeman. At the Hot Springs meeting the Council voted $25.00 for mounting paper and covers, and an additional $25.00 for clerical assistance. In order that this work may be made effective it ought to be continued without interruption. At the present rate of progress the material now on hand cannot be gotten into a proper working condition within ten years. It is to be hoped, therefore, that the Section will request the Council to make a like appropriation for next year.

The transfer of Ex-Treasurer Sheppard's books and papers and their disposition with the Historian, suggests the consideration of the advisability of having the books, correspondence files and other papers of all of the offices of the Association at large, and possibly of the sectional officers, transferred to the archives of the Association after the lapse of a given number of years. No doubt, much material that would shed considerable light upon the past history of our Association and of American pharmacy at large has been lost or even wilfully destroyed. The use of such material should be suitably restricted by special action of the Council or of the Association in general session assembled.

Another matter, which ought to receive the immediate attention of the Section, and later of the Association at large, is that of a library. Upon inquiry your historian has learned from the General Secretary that but few of the organizations which receive complimentary copies of the Proceedings send anything in exchange. This state of affairs is as undignified as it is extravagant. Your historian would therefore urge that this Section recommend two things to the General Session.
1. That the General Secretary be instructed to discontinue sending copies of the Proceedings to sister associations and other organizations that send no publications of their own in exchange.

2. That the office of librarian be established, and that a librarian be elected by the Council. In co-operation with the General Secretary and a member of the Finance Committee, it ought to be his duty to receive as large an exchange list as possible and thus to build up a library for the Association. Inasmuch as Washington is to be the home of the historical collections in the near future, it might be best to elect a librarian a member from that city. Whether such a library had better be placed with the Washington Section is a matter to which the Historical Section should give due thought before making a recommendation to the General Session.

If one reflects how many books and pamphlets have been lost to the Association in the past fifty years and more, simply because there was no one whose specific duty it was to preserve them, it takes but little imagination to construct a library of great value that we might have saved.

In accordance with a suggestion made by your Historian to the President, the Chairmanship of the Committee on our historical collections at Washington was transferred to a member resident in that city. We may expect, therefore, that our interests in that direction will be carefully guarded now that the National Museum is approaching its completion. As soon as the old National Museum building will have been reconstructed, it will be necessary to transfer our collections to Washington. At that time it may become necessary to appoint a custodian. Before this is done, however, a complete understanding with the Assistant Secretary of the Smithsonian Institute, who is in charge of the National Museum should be arrived at. Possibly this important matter can be turned over in due season to the Committee now looking after our interests at Washington. With a Librarian, a Custodian and an Historian, each an enthusiastic member in his particular field, our historical interests ought to be well taken care of in the future.

To recapitulate briefly. 1. The Section ought to ask for the continuation of the assignment of the regular allotment for historical work, as given above. 2. Our exchange ought to be placed on a dignified basis and the most ought to be made of this possibility to create a library. 3. The advisability of creating the office of Librarian ought to be carefully considered.

Respectfully submitted,

Edward Kremers, Historian.

The Chair called for action upon the report just read, and said there were a number of recommendations contained in it, which the Section should take cognizance of and act upon. He said if the Section was to be made as useful as it should be, the same attention would have to be paid to it as in other Sections. He called on the Historian, as being more familiar with his report to state the recommendations contained.

Mr. Kremers said he would reverse the order of the recommendations, taking the last first; and that recommendation was, that this Section consider the advisability of asking the Association in general session to take such steps as might be necessary to secure a desirable depository for, and permanent care of, the documents that had been accumulated since the year 1880, at least, by the Chairman of the Revision Committee of the U. S. P. He said he thought the Section should consider the advisability of having these documents turned over to the American Pharmaceutical As-
sociation, or whether, preferably, they should be turned over to the Smithsonian Institute. He thought some positive suggestion should be made along this line, and moved the adoption of this recommendation.

Mr. Hancock seconded the motion.

Mr. Wilbert thought it would be desirable to have these documents deposited somewhere where they would be preserved for fifty or a hundred years to come, as these papers were likely to be extremely valuable in the future. He doubted the policy of filing them with the Smithsonian Institute, and thought the Association should make provision to preserve them and have charge of them. He asked Historian Kremers if it would be possible for him to undertake the preservation of these documents along with the material already in hand, until suitable permanent quarters could be found in the future. He said he understood the Historian had facilities for storing matter in a fireproof building for the time being, and he thought it would be well to ask the Association to have this material so deposited, if agreeable to the Historian.

Mr. Kremers responded that for a number of years past they had been in communication with the Smithsonian Institution, asking for space in the old building whenever the new building was completed, for the deposit, and possibly the exhibition, of such material as might be or had been collected, and said promise had been made of such space in the old building when the material there house was transferred to the new building. He also said there was a committee of the general Association to look after this matter. Mr. Kremers went on to say that, since 1902, when this work was organized in Philadelphia, the Historian had collected a lot of material, which had been stored in a fire-proof building of the Library of the Wisconsin Historical Society. He thought this space might be made available for the time being.

Mr. Hancock suggested that, as this matter was in an embryonic state, it would be well to let it remain in the hands of the Historian until it could be more maturely considered. There was no particular haste about it. He asked the Historian whether, if the desired space were given, it would be the property of the Institution, or be at the demand and service of the Association.

Mr. Kremers replied that this matter had been left entirely open; that the Assistant Secretary of the Smithsonian Institution, with whom the correspondence has been had, had stated that it was impossible for the Institution to give any space at the present time, and it was not necessary to cross that bridge at this time. He asked that if any of the members knew of anyone having matter which would be a valuable contribution to the historic collection, but the title to which he did not wish to part with, he would be glad if they would say to such parties that this Section would be glad to take such material on deposit for the time being.

After some further discussion as to the disposal of this historical matter
until permanent arrangements could be made, participated in by Messrs. Hancock, Wilbert, Roehrig, the Historian and the Chairman, the Chair put the vote on the recommendation to request the Association in general session to take the necessary steps to have the criticisms of the last two Pharmacopoeias placed in charge of the Association, and it was carried.

Historian Kremers said the next recommendation was in reference to the creation of the office of Librarian, and he expressed the opinion that in such election the matter of permanent location of a Library should be considered, as, naturally, the Librarian should be chosen from such locality. He moved that the Section recommend to the Association in general session the creation of the office of Librarian.

This motion was seconded by Messrs. Hancock and Wilbert, and carried.

Mr. Kremers suggested that perhaps discussion might be had here as to the place where the Library was to be kept.

Mr. Wilbert thought the time was inopportune to discuss this question, until the Association had sufficient funds to provide and equip a building for the purpose.

Mr. Mayo did not agree with Mr. Wilbert in this view, and thought it would be wise to discuss the matter, in carrying out Historian Kremers' views. He said he took it that the duties of the Historian had already become so onerous as to make it desirable to divide them, and separate the duties of the Historian proper from those of Librarian. He thought it would be well for this Section to express its opinion as to the desirability of continuing the Library with the Historic Section. It might be that someone could be selected for Librarian who would aid in this work, and he for one would like to hear some expression of opinion in this respect.

Mr. Kremers said Mr. Mayo had given him credit for more work than he had done; that he had carefully avoided assuming the duties of a librarian, and had left in the hands of the General Secretary, who had charge of the exchange of volumes, etc., all such matters. The Secretary could turn over from year to year to the Librarian appointed such books as he received.

Mr. Mayo moved that it be declared the sense of the Section that Washington City would be a desirable place for the location of the proposed Library. He said it would eventually have to go to Washington, anyhow.

Mr. Wilbert said he would be willing to discuss Mr. Mayo's motion as far as desirability was concerned, but so far as practicability was concerned he doubted it very much.

Mr. Hays asked if it was not just a little bit absurd to say that Washington was a desirable place, when in the same breath it was said that it was not practicable to have it there. It seemed to him it was desirable to have it where it was practicable to have it. He thought the Historian could tell the Section something on this point.
Mr. Mayo said it was not impracticable to have it at Washington, and that he was under the impression that some members could be found in Washington who would say they would give house-room for the present small library.

Mr. Kremers said he had been thinking of Washington, and Washington only, as the proper place, and thought that, while it might be somewhat inconvenient to house a hundred volumes or so, somebody could be found in Washington who would do that; and if only once a Library was started, with, say, 500 volumes, or even less, he felt sure the Association would then provide a place for it. He also thought that the selection of a Librarian from Washington would be a good move, in that probably he could make suggestions as to the desirability of a location in Washington.

The Chair then put the vote upon the motion as made and it was carried.

Mr. Wilbert said that, considering the immediate future only, he wished to go back to the proposition of Madison, Wisconsin. There, he said, they had the most satisfactorily arranged pharmaceutical library in the country, and the best of systems, and the Historian could possibly get the Librarian of the University of Wisconsin to take an interest in this matter, and agree to house temporarily this collection of books, and then the Association would have at least in some one place in the United States a fairly respectable pharmaceutical library. It was common to speak of the United States as the greatest country on the face of the earth, and yet it had not a good pharmaceutical library. Surely there ought to be some place where, under the auspices of a good librarian, the nucleus of a pharmaceutical library could be gathered, and that nucleus developed into a real library.

Mr. Kremers said there was a practical difficulty which arose in this behalf. They had built a fine, fire-proof building at the University there, at an expense of over $600,000, and supposed they would have space enough for twenty-five years to come, but in twelve months' time they began to feel crowded. For this reason it was not an easy matter to secure from the Library Board permission to store this material, and he expressed the hope that he would not be asked to solicit more space than was necessary for the storing of the documents that must be kept in a fire-proof place.

Thereupon Mr. Mayo moved that the Chair appoint a committee of three to investigate the question of finding a location for the deposit of such books as were now on hand, and report at the next annual meeting, so that the members would be in a position to discuss this matter at that time. He suggested that temporary provision might be made for such material as the Association now had in the Surgeons' Library in Washington. He said he had a talk with the Chief Surgeon of that department on his way to this meeting, and he had informed him that the library had a complete collection of the pharmacopoeias of the world, and also of the
United States Pharmacopoeia, and he promised to make an exhibit of same at the Willard Hotel or at the Surgeons' Library during the Pharmacopoeial Convention in Washington next week, and he thought from his general attitude he would probably be willing to give space in the library for the time being for such matter as the Association had collected up to this time.

Mr. Kremers said he would be glad to second this motion, if Mr. Mayo would accept an amendment that the Librarian to be elected by the Association be made Chairman of this Committee.

Mr. Mayo agreed to this, and the motion was so put and carried.

The Chair stated that of course this committee could not be appointed until the Librarian was selected.

The Chair called for the report of the Secretary of the Section as the next order of business, but Mr. Dunn said that he had prepared no written report.

The Chair stated that the first paper on the list was one entitled, "History of Yerba Santa and Cascara Sagradal," by J. Winchell Forbes, but the author of the paper was not present.

Thereupon Mr. Wilbert moved that the paper be accepted and filed with the Historian, and this motion prevailed.

The next paper was an Autobiography of P. C. Candidus.

The Chair stated that he supposed all the members had seen this paper, as it was published in the pharmaceutical journals, and he had simply pasted it in a folder, with a letter from Mrs. Candidus, that it might be preserved, and he would ask that it be accepted in that way. So ordered.

A paper entitled, "A Suggestion to the Historical Section," was read by the author, Wilhelm Bodemann.

The Chair stated that this paper contained a good recommendation, viz.; for the establishment of "Veteran Associations" in different sections of the country. He thought if such a suggestion was acted upon, it would add to the Historic Section of the American Pharmaceutical Association.

Mr. Mayo thereupon moved that the Secretary be requested to transmit copies of this paper to the Secretaries of the several Branches, and this motion was seconded by Mr. Roehrig.

Mr. Kraemer said he was very much interested in Mr. Bodemann's paper, and would like to know what he considered a "veteran." Mr. Bodemann replied that the Association had started off by enrolling all those who were in business in Chicago before the Fire, and when these began to drop off, they made it at least twenty years in business, each member being required to furnish an autobiography.

Mr. Payne said that Mr. Bodemann had so much experience along this line that he would like to have him decide upon some line between "veterans" and ordinary men. Some of the members had not had a "fire," and he wanted to know who would be eligible for membership.
Mr. Bodemann responded that when a set of veterans got together, they ought to be "red-hot enough to start up a fire any time." (Laughter)

The Chair then put the vote upon Mr. Mayo's motion that a copy of the paper be sent to each of the Branches of the American Pharmaceutical Association, and it prevailed.

A paper entitled, "Historical Sketch of Idaho Pharmaceutical Association," by F. E. McClure, the Chair stated was one that had been given him at the Los Angeles meeting, and he had had it printed and put in shape to be filed. The author was not present and the paper might be referred to the Historian. So ordered.

"Historical Sketch of Colorado Pharmaceutical Association," a paper by S. L. Bresler, was not read at the moment, because of the author's absence. Later, Mr. Bresler came into the room, but said he did not care to read his paper, and suggested that it simply be filed. So ordered.

A paper entitled, "Historical Sketch of Texas Board of Pharmacy," by R. H. Walker, the Chair stated simply gave a synopsis of the work done by the Board, and was submitted to be filed of record. He stated that while the paper was brief, it was quite complete.

The next paper called for was one upon "The Cultivation and Distillation of Wormwood in Wisconsin," by J. E. Simons, and in the absence of the writer, Mr. Kremers passed the paper around among the members, that they might take a look at the figures it contained. He said that what he desired to say about this particular industry in Wisconsin was in regard to its origin. Wormwood had been distilled now in considerable quantities for more than fifty years, on a farm not far from Madison, by three generations of the Drew family. The grandfather of the present operator, who gave most of his time and attention to this present industry, lived in Vermont, if he remembered correctly, and was a distiller of rum. One day he discovered a neighbor's boy, a young man of from twenty to twenty-one years, coming home drunk, and he told his wife that he would never distill another drop of rum, as he considered it a contribution to the immorality of the community, and he would not make money in that way. This left him with a copper still on hand, and he felt that he had to make some use of it, and looking about him to find some such use, he hit upon the distillation of wormwood. Then when the family came West, this distillation of wormwood was continued, and had continued now for three generations. A hundred acres of wormwood were employed in a single season, in the distillation of this oil. Mr. Kremers went on to give a brief description of the crude, primitive methods employed in this distillation, following traditional lines, rather than lines of modern scientific development.

The Chair stated that the paper would take the usual course, and be filed with the Historian.

The Chair said the next subject for presentation before the Section was
that of some suggestions for the filing and binding of the U. S. P. Revision criticisms, by Mr. Kremers.

Mr. Kremers explained his subject in detail, with a practical demonstration of the improved filing system he had devised, showing how he could file fifty circulars at a time, keeping the circulars separate and distinct. He also explained his improved method of binding.

Mr. Wilbert thought it might be well in this connection, if practicable, to suggest to the Revision Committee that they change the style of their circulars. He said at the present time a great deal of the mimeograph-work was done on eight-and-a-half by eleven-inch paper, and it made a very satisfactory sheet also, and also the work of the Council of Pharmaceutical Chemistry. He thought it would be well to bring this to the attention of the Chairman of the Pharmacopœial Revision Committee, in the hope that they would adopt a sheet of this size, which would be more convenient and readily handled.

Mr. Payne congratulated Mr. Kremers on his suggestion. He said he had had considerable experience along this line. He thought that, while Mr. Wilbert's suggestion was a most excellent one, there was a reason for the use of the large sheet, and that was, in some classes of apparatus, to produce these reprints it was much more convenient to use a large sheet, and make one impression, as to the use of the smaller sheets involved more mechanical skill in the printing and filing. He thought this was the chief reason why the larger sheets were used.

Mr. Kremers said he did not mean to present his scheme as a justification for the large sheet. It was simply a way out of a very awkward situation; and for those who wanted to keep these records and make them useful, it furnished a method of disposing of them that was convenient and practicable.

And so the matter was passed.

The Chair stated that the next item on the program was "A Catalogue of Illustrations of Historical Apothecary Shops," by Edward Kremers.

Mr. Kremers said he would not read a paper, but simply desired to state in connection with the title that he had illustrations of apothecary shops running back to the Fourteenth Century. These illustrations, he said, were scattered all through pharmaceutical literature, mostly of the past century, and were found elsewhere as well. They were not readily available. Some of them were reproductions in works on civilization, and other books where they would be least expected. The object was to make this material available to the student of the drug-store. He said these illustrations were by far the most important documents to be had upon the historic development of the drug-store; that it was an interesting subject to those who were historically inclined, and the study had also an æsthetic side, because of the paintings and wood-cuts employed, as well as the more modern forms of reproduction.
The Chair stated that the next item upon the program was a contribution to the Rice Correspondence, by J. O. Schlotterbeck.

In the absence of the author, Historian Kremers presented this subject. He said the list contained letters written by Rice to Prescott. He was reminded of a remark made by the Historian of the Chicago Veterans' Association some months ago, to the effect that the best of history was autobiography, and that we had none of that by such men as Rice or Parrish or Procter. Although it had been a most difficult thing for the Historian of the Section to get at, the autobiography of these men was written in their letters. It was not in the most complete form, possibly, but anybody interested in these men would find these letters more charming than any autobiography could be. An autobiography had its value as supplemental to such letters, of course; but nothing could take the place of letters that were written with no purpose whatever as to the future. Mr. Kremers went on to say that the letters were arranged in chronological order, and explained how any addition to this file could be easily inserted at the proper place, under the arrangement observed. He also explained that, in case a member wanted to know something, say, about the development of Pharmacopœial revision in 1880, and it was found that Rice had written a letter to Prescott on such subject, it would not be necessary to send such member the whole volume and jeopardize it, but any single letter could be taken out, without danger of losing the rest. Continuing, Mr. Kremers urged upon the members present that if they had in their possession, or knew of others who had, letters of this character, that they bundle them up and send them to the Historian at once, and not wait to find some convenient time to go over them and arrange them in order; that it was his business to see that this was done, and he would gladly do it.

The Chair here filed with the Historian some Searby letters, presented by Albert Schneider, of San Francisco.

The Chair then called upon Henry Kraemer to present some additional Rice letters that he had in his possession.

Mr. Kraemer, in offering these letters to the Section, said that at the time of the meeting was approaching, he was reminded of a time in the life of a great leader of American pharmacy; and while he was not here then years ago, he was always with the Association in spirit, and he felt that he always would be, and he confessed that he felt as though he must have these letters with him at this meeting. He began to realize that life was fleeting, and that the only proper duty of one who really appreciated the services of Rice was to present such letters as he might be able to gather to the Association. He said he did not care to show some of these letters at this time, and that there were others he would get together as soon as possible. Mr. Kraemer went on to say that he believed it was the duty of all the members to present such letters to this Section. He said he also had some Searby, Hoffman and Ebert letters, which he would present.
Continuing, and referring to the proposition heretofore discussed of the selection of a site for a Library of the Association, Mr. Kraemer said he was reminded of a letter from Albert E. Ebert in connection with the Procter Memorial Fund. He quoted from it to show that Ebert favored the raising of a fund of $100,000, the interest only of which was to be used in defraying the expenses of the Association. He especially desired to point out that such a conservative man as Ebert thought it was feasible to raise such a sum. He thought that when it was realized that the American Society of Science was back of the proposed "Washington Memorial," which would certainly be built some day, to be used for the purposes of scientific bodies, it was a reminder that the time would come when there must be some central place for a History of American Pharmacy. He referred to this matter at this time because he was not sure but that the Monument Committee might see fit to have some more enduring monument than the one heretofore outlined. Mr. Kraemer closed by saying he was glad to present these letters to the Association at this time.

Mr. Mayo was here given the opportunity to present a matter of historic interest of local flavor. He said the City of Richmond was founded by William Byrd, of Westover, Virginia, and that he held in his hand a rare contribution to literature in the shape of a report by Col. Byrd—who might be called the first American author—in which he recorded his observations made during a survey of the boundary-line between Virginia and North Carolina. This book, he said, published in 1730, and entitled "History of the Dividing Line Between Virginia and North Carolina," was not only very interesting from an historical point of view, but was of special interest to pharmacists, as frequent reference was made to the flora of the country through which he passed, including many plants of medicinal interest. Mr. Mayo said he had in his library at home upwards of two hundred specimens of plants, such as were described in this book. His personal interest in the matter lay in the fact that the first Mayo in the United States was Major William Mayo, who was a surveyor on this line, and to whom Col. Byrd referred in his book as having laid out "the city afterwards called Richmond."

The Historian said that before the matter of Mr. Kraemer was disposed of, he wanted to call the attention of the members to the fact that those of them who might happen to have documents to which they were not willing to give publicity at this time should not be deterred from sending them in to the Historian for that reason, as he had more than one package in his possession, sealed and marked not to be opened until a given time. Any request of this sort would be duly respected, and nobody would see the contents of such books or documents, not even the Historian himself, until the date given had expired.

Mr. Hays contributed letters of Maisch, written in 1871 and 1872, and from Ebert, that he had found in the correspondence of J. B. Moore, a
prolific writer and one of the oldest members of the Association, who had died a few months ago, leaving a number of unfinished manuscripts and rough drafts of same. His son had invited him to go through this mass of matter, and he had found these letters. He also filed a clipping contributed by Mr. Mayo, in regard to the meeting in New York, which he said was history, because he believed it was the only thing that the New York people had had to say about the meeting. He also filed certain newspaper clippings, etc., and also a contribution in regard to the attitude of the Massachusetts Board of Pharmacy on the liquor question some years ago, with a typewritten statement of ex-President Whitney of his position on this question—a matter which provoked a great deal of criticism at the time.

The Historian used the contributions and statement made by Mr. Hays to emphasize again the importance of making contributions to this Section. Not all were commercially inclined, he said, so they could contribute to the Commercial Section, while others were not scientifically inclined, and could not contribute to the Section on Scientific Papers, but every member of the American Pharmaceutical Association was likely sometime to run across matter that would be of value to this Section, and he urged that such documents be filed with the Historian. He commended the course of Mr. Hays in bringing such material before the Section, with brief verbal explanation of its origin and character.

A paper entitled, "The History of the Arkansas Association of Pharmacists up to 1888," by W. W. Kerr, was reported by the Chair in form for filing.

A paper on "On Officers of the Nebraska Pharmaceutical Association to Date," by D. J. Fink, was likewise filed.

A paper entitled "A Brief History of Pharmaceutical Legislation in Pennsylvania," was presented in abstract by the writer, Louis Emanuel, and filed.

"A Brief History of the Massachusetts Board of Pharmacy," by J. F. Guerin, was presented in synopsis and referred for filing.

The Chair next called upon E. V. Howell, of North Carolina, to present a series of papers on the program, and Mr. Howell said he would present these in brief abstract, beginning with the last one on the list. He presented papers on the following subjects:

"Yaupon, the Tea of the Aborigines of America, and its Caffeine Content."

"Sketch of William Bartram, of Pennsylvania (Botanist, 1730-1823").

"Sketch of John Clayton, of Virginia (Botanist, 1685-1773").

"Wheaton's Method of making Quicksilver Ointment, 1808."

A paper by W. C. Coker, "Sketch of Thomas Walter of South Carolina, (Botanist, 1730-1778)" was also filed; as was also a paper entitled, "A list of Medical Plants grown by W. C. Coker, University of North Carolina Arboretum."
A paper entitled, "A Brief History of the Indiana Pharmaceutical Association," by Maurice P. Schwartz, was received and filed.

"A Condensed History of the Wisconsin Pharmaceutical Association," by E. B. Heimstreet, was a paper likewise received and filed.

The next paper on the program was one entitled, "Presidents of Arkansas Association of Pharmacists," by Miss Mary A. Fein, which was received and filed.

The Chair had called upon E. J. Kennedy, of New York, to present some caricatures from the files of the Pharmaceutical Era.

Mr. Kennedy said he had not prepared a paper on this subject, as he had not the time, but the Historian had asked him by letter to say something on the subject of such caricatures, and he had run across some of these sketches and had brought them along. He exhibited a sketch of Henry Canning, caricatures of four presidents of Pharmaceutical societies in New York, and of Messrs. Anderson, Sheppard and others.

"History of U. S. P: Drugs" was the title of a paper by John Uri Lloyd, which was read by title and filed.

A paper upon "Proceedings of the Silver Jubilee Meeting" was likewise received and filed.

The next paper called for was one by Mr. J. F. Hancock, entitled, "History of the Maryland Pharmaceutical Association."

Mr. Hancock said he would not read the paper, as it was scarcely worth while to take the time of the Section, but it would be put in form and presented to the Historian. He said that the inspiration of the State Pharmaceutical Association to begin with was this Association; that a committee was appointed to consider the subject of legislation, and the draft of a model law was presented, which was gotten up with great care, and Maisch contributed largely to it. It was presented to the Association and very vigorously discussed, but it was considered not to apply to the needs of all the States, and that there would be need of modification in many of the States adopting a pharmacy law. This was 1867, and was the beginning of many of the State Pharmaceutical Associations. The first Pharmaceutical Association founded was that of New Jersey, in 1870. The Maryland Association was not formed until 1883, and the first law that was passed (1872) applied only to the city of Baltimore.

The Chair stated that the next paper on the program was one contributed by Otto Reubenheimer, entitled, "Biography of Friedrich Hoffman, originator of Hoffman's Anodyne," and the other, "Biography of Karl Friedrich Mohr." He said the author was not ready to present these papers, and that he understood they would be filed with the Historian later.

The Chair stated that this concluded the list of papers before the Section.

Mr. Cliffe said he was constrained to admit delinquency on his part in regard to the request preferred by the Historian, in relation to some ma-
nomination and election of officers.

Mr. Hancock presented a photograph of T. Roberts Baker, of Virginia, a former officer of the Association, and said he had gotten some important data that he would use in writing out a sketch of Baker. Baker, he said, was born in Richmond in 1825, and at the age of fifteen entered a pharmacy in the City of Richmond. He graduated from Philadelphia College of Pharmacy in 1852, the year this Association was organized, and returned to Richmond and went into business. In 1852 the firm of Mead & Baker was organized, and became the well known establishment. Later on, he entered the manufacturing business.

The Chair brought up the question of an appropriation for the Historical Section, but the Historian expressed the opinion that this could be arranged through the Council, without action by the Section, and Mr. Wilbert concurred in this view.

The Chair called for nomination of officers of the Section as the final order of business.

Mr. Wilbert proposed the name of John A. Dunn, of Brooklyn, the present Secretary of the Section, for the office of Chairman, but Mr. Dunn declined, on account of age and present infirmities. Mr. Wilbert said he had in mind this possible objection, and suggested that Mr. Raubenheimer, an inveterate worker, might be nominated for Secretary, and Mr. Dunn would be saved all writing. Mr. Dunn insisted upon his declination, however, and the matter was not pressed.

Thereupon Mr. Cliffe nominated J. L. Lemberger, of Lebanon, Pennsylvania, for Chairman, and this motion had several seconds.

On motion, nominations for Chairman were closed, and Mr. Hancock moved that the Secretary cast the affirmative ballot of the Section electing Mr. Lemberger its Chairman. This motion was put and carried, the Secretary announced that he had cast the ballot as directed, and the Chair declared Mr. Lemberger duly elected Chairman of the Section for the ensuing year.

Mr. Wilbert nominated Otto Raubenheimer, of Brooklyn, for the office of Secretary. This nomination was seconded, and on motion, nominations were closed. On motion of Mr. Hays, seconded by Mr. Wilbert, the Secretary was directed to cast the affirmative ballot of the Section electing Mr. Raubenheimer to the office of Secretary. He announced that the ballot had been cast, and the Chair declared Mr. Raubenheimer duly elected.

Mr. Lemberger said he did not object to giving his time and labor to the American Pharmaceutical Association, but fully realized in accepting the position of Chairman of the Historic Section that there must be hearty co-operation on the part of the members in order to insure its success.
He knew of the good work that had been done in the past, and he wanted to ask the aid of the members in the work of the Section for the coming year.

Mr. Hays nominated Edward Kremers to succeed himself in the office of Historian, and this motion was seconded by Mr. Wilbert and Mr. Howell. On motion, nominations for Historian were closed, and the Secretary directed to cast the affirmative ballot of the Section electing Mr. Kremers to this office. The Secretary announced that he had cast the ballot as directed, and the Chair declared Mr. Kremers duly elected Historian of this Section.

Mr. Howell stated that, at the Los Angeles meeting last year, the Section had passed a resolution to the effect that the Association be asked to appropriate $100 for the use of the Historical Section, and he wanted to know the fate of that matter, and whether the appropriation was made by the Council or not.

The Chair admitted that he did not know its fate.

Mr. Kremers suggested that the Section renew this request, and Mr. Hays duly seconded, so moved, and it was ordered that the Association be asked to appropriate $100 for the use of the Section.

Mr. Wilbert moved that the Chairman of the Section, who was now a member of the Council, see that the matter of appropriation be brought before the Council. He said he thought this would be a good work for the Chairman to do.

No action was taken upon this suggestion.

The Chair stated that if there was no other matter to be brought before the Section, a motion to adjourn would be in order.

Mr. Wilbert so moved, and the Section stood adjourned.
ENTERTAINMENTS AT THE FIFTY-EIGHTH ANNUAL MEETING.

As was to be expected, the well-known Virginia hospitality was in evidence everywhere, from the highest state and city officials to the humblest citizen, and those members who ten years previous had attended the meeting in Richmond fully realized that the welcome accorded them was as natural as the glorious sunshine of the southern sky.

The President's reception, held at the Hotel Jefferson, was, as usual, largely attended and much enjoyed, for Dr. Rusby and his good lady did the honors of the evening in a charming manner. His Excellency, Governor Mann, also tendered the visitors a reception at his official mansion, where he and Mrs. Mann proved themselves genial hosts.

Numerous card parties and sight-seeing auto rides had been arranged for the visiting ladies, who on one day were also taken in cars to the battlefield of Seven Pines. One of the leading features of the week was a real southern picnic, held at Lakeside Park, where a bountiful supply of refreshments was served and those in attendance delightfully entertained by a genuine negro minstrel show.

Much amusement was afforded by the morning visits to the Police Court, where "Squire John" reigns supreme and administers justice daily, dealing out punishment and advice in his own peculiar and inimitable way to the malefactors brought before him.

Many thanks are due Local Secretary T. Ashby Miller and Mrs. Miller and their associates on the Committee of Arrangements.

One of the most interesting and at the same time instructive features of the meeting was the exhibition of a large number of living medicinal plants, many of which furnish official and others unofficial but popular drugs. To many of the visiting members this was the first opportunity of seeing specimens of plants heretofore known to them by name only, and the Association is under many obligations to the parties who so generously contributed their time and labor to make the exhibition a success.

The collection was chiefly contributed by the United States Bureau of Plant Industry, Messrs. Eli Lilly & Co. of Indianapolis, Professor Henry Kraemer and Professor H. H. Rusby. The New York Botanical Garden sent specimens of plants yielding cinnamon, camphor, vanilla, black pepper, coca, tea and coffee. Dr. Hoell Tyler sent from Redlands, Cal., flowering specimens of Eriodictyon or Yerba Santa. Professor L. F. Sayre
sent from Kansas a specimen of Brauneria (Echinacea) angustifolia. Professor E. G. Eberle sent from Texas, Cynoglossum cicuta, two specimens of Artemisia and a number of plants which arrived too late to permit of determination and labeling. Professor E. V. Howell sent from Chapel Hill, N. C., Trillium erectum, Arum and Podophyllum. Although a few specimens were duplicated by different contributors, most of them were represented by solitary specimens.

Spigelia or pink root was sent by the Bureau, Lilly & Co. and Howell. Two specimens of Phlox which are used as adulterants of pink root were sent by Lilly & Co., Kraemer and the Bureau, and the latter sent Ruellia ciliocosa, which is another important adulterant of this drug. Digitalis was sent by Kraemer and Lilly & Co. Peppermint, spearmint, elecampane, Hepatica triloba and Porteranthus (Gillenia) trifoliata by the Bureau and Lilly & Co.; Hydrastis by the Bureau, Kraemer and Lilly & Co.; tansy, lily of the valley, blue flag, calamus, burdock, geranium, cimicifuga, blood-root, sumach and arum by the Bureau, Lilly & Co., and Rusby; belladonna and Rumex crispus by the Bureau and Rusby; black hawk, wild cherry, white oak, flowering dogwood, sassafras (from both stamine and pistillate plants), mandrake and Triosteum perfoliatum by Lilly & Co., and Rusby.

In addition to the above plants the Bureau sent the following:

Cypripedium hirsutum, Hyoscyamus niger, Thymus vulgaris, Artemisia absinthium, Carum carvi, Lavandula vera, Chelone glabra (Balmony), Levisticum officinale, Nepeta cataria, Foeniculum vulgare, Mentha citrata, Mentha crispa, Mentha longifolia, Pyrethrum cinerarafolium (Dalmatian Insect Powder), Monarda fistulosa, Baptisia tinctoria, Glycyrrhiza glabra, Pycnanthemum abescens, Rubia tinctoria (Madder), Althaea officinalis, Salvia officinalis, Rhamnus purshiana, Panax quinquefolium (Ginseng), Valeriana officinalis, Iris florentina, Colchicum autumnale, Conium maculatum, Collinsinia canadensis, Calendula officinalis, Caulophyllum thalictroides, Aristolochia serpentaria, Chamaelirium luteum.

Messrs. Lilly & Co. sent Odostemen (Berbis) nervosa, one of the Oregon grape roots, Hepatica acutiloba, shepherd’s purse, Polemonium, Mitchella, Jeffersonia, Senecio aureus, Bicuscula canadensis or squirrel corn, Gaphalium obtusifolium, Aesculus glabra, Cercis, Hydrangea, Trillium, Equisetum hyemale, Aralia nudicaulis, Asarum canadense, A. reflexum, yarrow, tulip trees, mullein, Virginia creeper, paw-paw, witch hazel, dandelion, poke root, beech drops and common plantain.

Professor Kraemer sent aconite, pleurisy root, blue passion-flower, yellow jasmine, male fern, senega and Brauneria (Echinacea) purpurea.

Dr. Rusby sent Xanthorrhiza, the pink-flowered form of Cornus florida, two species of Solomon’s seal, Rumex obtusifolia, butternut, Veratrum viride, Dracontium, scopola, Euonymus, white willow, moon seed and Actaea alba.
## APPENDIX.

### ALPHABETICAL LIST OF NAMES OF MEMBERS FROM WHOM MONEY HAS BEEN RECEIVED BY THE TREASURER FOR ANNUAL DUES OR CERTIFICATES, FROM JULY 1, 1909, TO JULY 1, 1910.

CONSTITUTION AND BY-LAWS
OF THE
AMERICAN PHARMACEUTICAL ASSOCIATION.

CONSTITUTION.

ARTICLE I. This Association shall be called the “American Pharmaceutical Association.” Its aim shall be to unite the educated and reputable Pharmacists and Druggists of America in the following objects:

1. To improve and regulate the drug market by preventing the importation of inferior, adulterated, or deteriorated drugs, and by detecting and exposing home adulterations.

2. To encourage such proper relations among Druggists, Pharmacists, Physicians, and the people at large, as may promote the public welfare, and tend to mutual strength and advantage.

3. To improve the science and art of Pharmacy by diffusing scientific knowledge among Apothecaries and Druggists, fostering pharmaceutical literature, developing talent, stimulating discovery and invention, and encouraging home production and manufacture in the several departments of the drug business.

4. To regulate the system of apprenticeship and employment, so as to prevent, as far as practicable, the evils flowing from deficient training in the responsible duties of preparing, dispensing and selling medicines.

5. To suppress empiricism, and to restrict the dispensing and sale of medicines to regularly educated Druggists and Apothecaries.

7. To create and maintain a standard of professional honesty equal to the amount of our professional knowledge, with a view to the highest good and greatest protection to the public.

ARTICLE II. This Association shall consist of active, life, and honorary members, and shall hold its meetings annually.

ARTICLE III. The officers of the Association shall be a President, three Vice-Presidents, a General Secretary, a Treasurer, and a Reporter on the Progress of Pharmacy, all of whom shall be elected annually; also a Local Secretary to be elected by the Council. They shall hold office until an election of successors.

ARTICLE IV. All moneys received from life membership, together with such funds as may be bequeathed, or otherwise donated to the Association, shall be invested by the Treasurer in United States Government or State securities, the interest of which for any current year only may be used by the Association for its expenses.

ARTICLE V. Every proposition to alter or amend this Constitution shall be submitted
in writing, and may be balloted for at the next Annual Meeting, when, upon receiving
the votes of three-fourths of the members present, it shall become a part of this Con-
stitution. Any proposition to amend the Constitution for the purpose of permitting the
expenditure of the permanent invested funds of the Association, shall require a majority
of seven-eighths for its passage.

BY-LAWS.

CHAPTER I.

Of the Election of Officers.

ARTICLE I. A Nominating Committee shall be annually chosen, whose duty it shall
be annually, at the meeting, to select candidates for the offices of President, three Vice-
Presidents and three members of the Council.

ARTICLE II. The Nominating Committee shall submit the names of three persons as
candidates for each of the offices of President, First Vice-President, Second Vice-Pre-
dent, Third Vice-President, and three members of the Council. These names are to be
submitted by the General Secretary by mail to every member of the Association, together
with a request that the member indicate his preference on a ballot enclosed for that
purpose, and return the same by mail within one month after the adjournment of the
annual meeting.

ARTICLE III. The ballots received as indicated in the preceding article are to be sent
by the General Secretary to a Board of Canvassers, composed of three members to be
appointed by the President, who shall count as votes in the annual election only the
votes of those members whose dues have been paid for the current year, and who in turn
shall certify to the General Secretary the result of the election, after which the latter shall

ARTICLE IV. The officers thus elected by a plurality of the votes cast shall be
installed at the final general session of the next annual meeting.

ARTICLE V. The Reporter on the Progress of Pharmacy, the Treasurer and the Gen-
eral Secretary shall be elected annually by the Council.

CHAPTER II.

Of the President and Vice-Presidents.

ARTICLE I. The President shall preside at all general sessions of the Association, ex-
cept those of the special Sections, as hereinafter provided. In the event of his absence
or inability to serve, one of the Vice-Presidents, or in the absence of all a President pro
tempore, shall perform the duties of President.

ARTICLE II. In the absence of the General Secretary, the President shall appoint a
Recording Secretary pro tempore.

ARTICLE III. At the sessions the President shall take the chair at the proper time;
announce all business; receive all proper motions, resolutions, reports and communica-
tions, and order the vote upon all proper questions at the proper time.

ARTICLE IV. In all balloting, and on questions upon which the ayes and nays are
taken, the President is required to vote, but his name shall be called last; in other cases
he shall not vote, unless the members be equally divided, or unless his vote, if given to
the minority, will make the decision equal; and in case of such equal division, the mo-
tion is lost.
CHAPTER

BY-LAWS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION. 1319

ARTICLE V. He shall enforce order and decorum; it is his duty to hear all that is spoken in debate, and in case of personality and impropriety he shall promptly call the speaker to order. He shall decide all questions of order, subject to the right of appeal, unless in case where he prefers to submit the matter to the members; decide promptly who is to speak when two or more members rise at the same moment, and be careful to see that business is brought forward in proper order.

ARTICLE VI. He shall have the right to call a member to the chair, in order that he may take the floor in debate. He shall see that the Constitution and By-Laws are properly enforced.

ARTICLE VII. He shall appoint all committees, not provided for in the By-Laws or otherwise directed by the Association.

ARTICLE VIII. He shall sign the certificates of membership, and countersign all orders on the Treasury. He shall obey the instructions of the Association, and authenticate by his signature, when necessary, its proceedings.

ARTICLE IX. He shall present at each annual meeting an address, embodying general scientific facts and events of the year, or discuss such scientific questions as may to him seem suitable to the occasion.

CHAPTER III.

Of the General Secretary.

ARTICLE I. The General Secretary shall be elected annually and shall receive from the Treasurer an annual salary not to exceed $1200, and the amount of his expenses incident to the meeting, in addition to his salary.

ARTICLE II. He shall keep fair and correct minutes of the proceedings of the general sessions, and carefully preserve, on file, all reports, essays, and papers of every description presented to the Association, and shall be charged with the necessary foreign and scientific correspondence, and with editing, publishing, and distributing the Report of the Proceedings of the Association, under the direction of the Council.

ARTICLE III. He shall read all papers handed him by the President for that purpose, shall call and record the ayes and nays, whenever they are required to be called; shall notify the chairman of every standing and special committee of his appointment, giving him a list of his colleagues, and stating the business upon which the committee is to act. He shall notify every member at least two weeks in advance of the time and place of each annual meeting.

CHAPTER IV.

Of the Local Secretary.

ARTICLE I. The Local Secretary shall reside at or near the place where the next annual meeting of the Association is to be held.

ARTICLE II. He shall assist the General Secretary in his duties; shall co-operate with the Council and any Local Committee in making arrangements for the annual meeting; shall correspond with the chairmen of the several committees, and with other members, in advance of the meeting, for the promotion of its objects, and shall have the custody of specimens, papers, and apparatus destined for use or exhibition at the meetings.
Article III. An exhibition of objects interesting to pharmacists, may be held each year, should the Council so determine, under the direction of the Local Secretary and the Committee on Commercial Interests.

CHAPTER V.

Of the Treasurer.

Article I. The Treasurer shall collect and take charge of the funds of the Association, and shall hold, sign, and issue the certificates of membership.

Article II. He shall pay no money except on the order of the General Secretary, countersigned by the President, and accompanied by the proper vouchers.

Article III. He shall report to the Council, previous to each annual meeting, the names of such members as have failed to pay their annual dues for three years.

Article IV. He shall present a statement of his accounts at each annual meeting of the Council, that they may be audited; he shall receive an annual salary not to exceed $750, and the amount of his expenses incident to the meeting, in addition to his salary.

Article V. The Treasurer, in order that he may qualify for the office to which he has been elected, shall file a good and sufficient bond or bonds to the amount of $15,000 with the Chairman of the Council for the faithful performance of his duties as Treasurer, this bond or bonds to be signed and executed by a Trust Company acceptable to the Council.

CHAPTER VI.

Of the Reporter on the Progress of Pharmacy.

Article I. The Reporter on the Progress of Pharmacy shall be elected annually, and shall receive from the Treasurer for his services an annual salary not to exceed $750.

Article II. All journals and volumes received in exchange for the Proceedings by the General Secretary, and such other journals as shall be deemed necessary, shall be sent to him by that officer for use in the compilation of his report; for all of which he shall be held responsible until returned to the General Secretary for preservation.

Article III. From these and other available sources, he shall prepare a comprehensive report on the improvements and discoveries in Pharmacy, Chemistry and Materia Medica, and the collateral branches of knowledge; together with such statistical and biographical notices as will furnish an epitome of the progress and changes in the science and practice of Pharmacy, and of its votaries, at home and abroad.

Article IV. The Report on the Progress of Pharmacy shall commence with July 1st of the preceding year, and end with June 30th of the year in which it is submitted, shall be written in a form fitted for the printer, and shall be presented completed at the annual meeting, unless such meeting is held previous to August 1. An introduction or synopsis of the Report is to be presented to the Section on Scientific Papers.

Article V. In case of the illness or other inability of the Reporter to carry on the work of the report, the General Secretary and the Chairman of the Council shall be required to make the best arrangements they can command to continue the work to its completion.
CHAPTER VII.

Of the Council.

ARTICLE I. The business of the Association which is not of a scientific character shall be in charge of a Council, which is empowered to transact business for the Association between the times of meeting, to reduce any appropriations that have been made, whenever in their judgment the current receipts are not sufficient to allow the expenditure, and to perform such duties as may from time to time be committed to them by the Association; their acts, however, being subject to revision by the Association. Any member of the Association may attend the meetings of the Council, and may, by vote of the Council, be permitted to speak on any subject under discussion.

ARTICLE II. The Council shall consist of ex-officio members; one member from each local branch of this Association and nine other members, selected from such members as have had at least three years' membership in this Association, shall be elected by ballot by the Association in the following order: Three of them to serve for one year, three for two years, three for three years. At each subsequent annual meeting, three members shall be elected to take the places of those whose terms will then expire, to serve for the term of three years.

ARTICLE III. The President, Vice-Presidents, General Secretary, Local Secretary, Treasurer, Reporter on the Progress of Pharmacy, Editor of the Bulletin, the Chairmen of the Sections of the Association, the Secretary of the Council, and the Historian of the Association shall be ex-officio members of the Council.

ARTICLE IV. Vacancies which may occur in the Council shall be filled for the unexpired term or terms by the Association at its next annual meeting.

ARTICLE V. The officers of the Council shall consist of a Chairman, Vice-Chairman, and a Secretary, to be elected by ballot annually by the Council.

ARTICLE VI. The Council shall be charged with the examination of the credentials of delegates, and the transaction of unfinished business of the Association from one annual meeting to another, and with collecting, arranging, and expediting the business of the Association during the sessions of the annual meeting.

ARTICLE VII. There shall be elected annually by ballot, by the Council, three standing committees of the Council—a Committee on Membership, a Committee on Publication, and a Committee on Finance—to whom shall be referred such duties as are appropriate to their respective functions, as the Council shall direct; they shall report annually to the Council, and at such other times as the Council may direct.

Whenever deemed advisable by the Council, it shall alter the publication of each edition of the National Formulary appoint a committee of fifteen members from the general membership of the Association, which committee shall have charge of the revision of the Formulary. This committee shall report annually or as often as required to the Council and shall continue to serve until the edition for which it was appointed has been completed. Vacancies occurring in this committee shall be filled by the Council as quickly as is expedient.

ARTICLE VIII. Section 1. The Council shall have charge of the revision of the roll and the publication of the Proceedings.

Section 2. The Secretary of the Council shall read at each of its sessions the names of those candidates for membership which have been proposed, when a vote of two-thirds shall be sufficient to recommend them to the Association.
Section 3. The Council shall decide upon any objections which may be presented to them (which must be in writing, with the member's name attached), referring to the fitness of the candidates for membership; and no name shall be voted on by the Association without first receiving the approval of the Council.

Section 4. The Committee on Membership shall report at each annual meeting of the Council a revised roll of members, with appropriate notices of deceased members.

Article IX. The Council shall furnish to each member of the Association not in arrears, one copy of the annual Report of the Proceedings, which publication shall contain the correct roll of members, full minutes of the several sessions of the Association and of the Sections, a complete synopsis of the minutes of the Council, the reports of the President and Committees, together with such addresses, scientific papers, discussions, notices of new processes and preparations, as it may deem worthy of insertion. It shall also fix the price at which the Proceedings may be sold.

Chapter VIII.

Of Membership.

Article I. Every pharmacist and druggist of good moral and professional standing, whether in business on his own account, retired from business, or employed by another, and those teachers of Pharmacy, Chemistry and Botany, who may be especially interested in Pharmacy and Materia Medica, also editors and publishers of pharmaceutical journals, who, after duly considering the objects of the Association and the obligations of the Constitution and By-laws, subscribe to them, are eligible to membership; provided that any person whose name has been dropped from the roll of members for non-payment of dues may be readmitted after having again made application in regular form, the application being accompanied by the usual fee; or he may be readmitted, without such application, on payment of all back dues; in the latter case his membership shall date from the time when he first joined the Association, as previously printed in the Roll of Members, and notice of such action shall be inserted in the adendum to the Treasurer's report.

Article II. Every application for membership shall require the endorsement of two members of the Association in good standing, and each applicant must receive the affirmative vote of three-fourths of the members of the Council for election, after which his membership shall be completed by his signing the Constitution and By-laws and paying the annual dues for the current year. Any newly-elected member, upon the payment of the annual dues for the year in which he is elected, shall be entitled to the annual volume of the Proceedings and all publications of the Association that are distributed to its members during the year. Any applications for membership made during the fiscal year viz., between July 1 of one year and July 1 of the following year shall be considered as of the current fiscal year; except that persons applying on or after March 1st shall not be required to pay the annual dues for that year, but if they do pay such dues they shall receive all the publications to which members are entitled for the year.

Article III. Every member shall pay in advance to the Treasurer the sum of Five Dollars as his yearly contribution, and by neglecting to pay said contribution for three successive years he may be dropped from the Roll.

Article IV. Any member of the Association who shall pay to the Treasurer the sum of $100.00 during the first year of his connection therewith, and also any member not in arrears, who after ten years shall pay the sum of $75.00, or after fifteen years the sum of $50.00, or after twenty years the sum of $25.00, and any member who may have paid annual dues for thirty-seven consecutive years, shall become a life-member, and shall be exempt from all future annual contributions.
ARTICLE V. All local organizations of Pharmacists shall be entitled to five delegates as their representatives in the annual meetings, who, if present, become members of the Association on signing the Constitution and paying the annual contribution for the current year: Provided, that the provisions of this article shall not be so construed as to reinstate any member whose name shall have been dropped from the roll for non-payment of dues; nor shall any one who has been expelled from the Association be received as a delegate. All credentials shall be sent to the General Secretary at least two weeks in advance of the annual meeting.

ARTICLE VI. Members shall be entitled, on the payment of Three Dollars or of Five Dollars, to receive from the Treasurer respectively a paper or parchment certificate of membership signed by the President, one Vice-President, the General Secretary, and the Treasurer.

ARTICLE VII. Resignations of membership shall be made in writing to the General Secretary or Treasurer, but no resignation shall be accepted from any one who is in arrears to the Treasury.

All resignations shall be acknowledged in writing by the officer who receives them, and shall be reported to the Council.

ARTICLE VIII. Any member may be expelled for improper conduct, or the violation of the Constitution, By-Laws, or Ethics, adopted by the Association, but no person shall be expelled unless he shall receive for expulsion two-thirds of all the votes cast at a general session.

ARTICLE IX. Pharmacists, chemists, and other scientific men who may be thought worthy the distinction, may be elected honorary members. They shall not, however, be required to contribute to the funds, nor shall they be eligible to hold office or vote at the meetings.

CHAPTER IX.

Of Meetings and Sections.

ARTICLE I. The meetings shall be held annually: Provided, that in case of failure of this, from any cause, the duty of calling the Association together shall devolve upon the President, or one of the Vice-Presidents, with the advice and consent of the Council.

ARTICLE II. To expedite and render more efficient the work of the Association, five Sections shall be formed, as follows: 1. Section on Scientific Papers; 2. Section on Commercial Interests; 3. Section on Practical Pharmacy and Dispensing; 4. Section on Pharmaceutical Legislation and Education; 5. Section on Historical Pharmacy.

ARTICLE III. The business of the Association shall be arranged so that the labors of each Section shall be considered only at the session or sessions to which they are especially assigned.

ARTICLE IV. The first, second and last sessions of the annual meeting shall be devoted to the general business of the Association, and sufficient time shall be assigned to the Association at the beginning of all other sessions to read the minutes of Council, act on the report of Council on membership, and receive propositions for amendments to the By-Laws.

ARTICLE V. At the third session the business of the Section on Commercial Interests shall be considered.

ARTICLE VI. At the fourth and fifth sessions the Section on Pharmaceutical Legislation and Education shall consider the business assigned to that Section.
BY-LAWS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

ARTICLE VII. The sixth and seventh sessions shall be devoted to the reading of Scientific Papers and the discussions thereof.

ARTICLE VIII. The eighth and ninth sessions shall be devoted to the subject of Practical Pharmacy and Dispensing.

ARTICLE IX. The tenth session shall be devoted to the subject of Historical Pharmacy.

ARTICLE X. A Chairman and a Secretary shall be elected by ballot by each Section to serve at the sessions of said Section. The minutes of each session, together with all documents and papers which belong to each Section, must be placed as soon as possible in the hands of the General Secretary for publication and safe-keeping.

ARTICLE XI. The Chairman of each Section shall preside at each of its sessions, and shall prepare a short address treating upon the subjects connected with his Section, to be read before the Section at the annual meeting.

ARTICLE XII. There shall be elected by each Section a Committee, of which the Chairman of the Section shall be Chairman, to whom shall be delegated the duty of arranging in advance the business to come before the Section at the next annual meeting; these committees in each case becoming Standing Committees of the Association.

ARTICLE XIII. The order of business at the first session of each annual meeting shall be as follows:

Section 1. Promptly at the time named in the notice issued for the meeting, the President, or, in his absence, one of the Vice-Presidents, or, in their absence, a President pro tempore, shall officiate.

Section 2. In the absence of the General Secretary, the President shall appoint a Recording Secretary pro tempore, who shall perform the duties of the General Secretary until his arrival.

Section 3. Nineteen members shall constitute a quorum for the transaction of business.

Section 4. The President's address may then be read, after which the Council shall report the list of properly accredited delegates.

Section 5. Reports of Committees shall be presented, read by their titles, synopsis or in full, and laid on the table for future consideration.

Section 6. The minutes of the Council shall be read in full at the annual meeting of the Association, and its acts, if approved, shall be sustained by a vote of the majority of the members present; or, if disapproved by a majority of the members present, its acts shall be revised, so as to be acceptable to the Association.

Section 7. The President shall call the roll of States, the Territories, District of Columbia and the Provinces of Canada, requesting the members present from each State or Territory to appoint two members, the persons so selected to act as a Committee to nominate officers for the Association, and members of the Council for the ensuing three years; in addition to which the President shall appoint five members from the Association at large to act with the Committee. Delegates who are not members must complete their membership before they are eligible to serve on the Nominating Committee.

Section 8. Incidental business.

ARTICLE XIV. The order of business at the second general session at each annual meeting shall be as follows:

Section 1. The President shall call the Association to order.

Section 2. The Secretary shall read the minutes of the preceding session, which may be amended, if necessary, and shall then be approved.

Section 3. The Report of the Committee on Nominations shall be read.

Section 4. Reading of the Minutes of the Council.

Section 5. Reading of the Reports of the Treasurer and General Secretary.
Section 6. Reports of Standing Committees shall be read.

Section 7. Reports of Special Committees shall be read.

Section 8. Incidental business.

Section 9. Adjournment subject to the call of the President.

ARTICLE XV. The order of business for the sessions of the Sections shall be determined by each Section for itself.

ARTICLE XVI. No money shall be appropriated from the Treasury by any of the Sections.

ARTICLE XVII. At the last general session of the Association the newly-elected officers of the Association shall take their respective places.

ARTICLE XVIII. The Council may arrange for such social sessions, to be held after the adjournment of the last general session, as it may deem expedient, but no business of the Association can be transacted at these social sessions.

CHAPTER X.

Of Committees.

ARTICLE I. There shall be appointed or elected eleven Standing Committees as follows: a Committee on the U. S. Pharmacopoeia and a Committee on Transportation, each to consist of ten members; a Committee on the Pharmaceutical Syllabus, to consist of seven members; a Committee on Time and Place of Meeting, a Committee on Commercial Interests and a Committee on Pharmaceutical Education and Legislation, each to consist of five members; a Committee on Scientific Papers, a Committee on Practical Pharmacy and Dispensing, a Committee on Historical Pharmacy, a Committee on Ebert Prize, and a Committee on General Prizes, each to consist of three members.

ARTICLE II. The Committee on Commercial Interests shall be elected by the Section on Commercial Interests. It shall be charged with the work of arranging in advance the business to come before the Section at the next annual meeting. It shall propose each year a subject for discussion at the meetings of the State Associations, and at the following annual meeting of this Association shall present a report of the action of the State Associations upon the subject proposed.

ARTICLE III. The Committee on Scientific Papers shall be elected by the Section on Scientific Papers. It shall arrange the business of the Section, and shall report a number of questions of scientific and practical interest, the answers to which may advance the interests of Pharmacy, and shall procure the acceptance of as many such questions for investigation as may be practicable.

ARTICLE IV. Any person desiring to submit a paper to the Association shall present to the Chairman of the particular Section to which it refers, at least ten days prior to the meeting, an abstract of said paper, indicative of its contents, and consisting of not less than fifty nor more than two hundred words.

This abstract shall be printed as a part of the programme. The paper itself must be submitted to the officers of the Section previous to the first session. Not more than ten minutes shall be allowed for the presentation of any paper, unless by unanimous consent of the Section.

ARTICLE V. The Committee on the Ebert Prize, which shall be appointed by the Chairman of the Section on Scientific Papers, shall, at the next annual meeting after the one at which essays are presented, determine which, if any of them, has met the requirements of the founder of the prize. In all respects it shall be governed by the stipulations expressed by the donor.
ARTICLE VI. The Committee on General Prizes, which shall be appointed by the President, shall, at the next annual meeting after the one at which the papers are presented, determine which, if any of them, are worthy of prizes, and decide upon the relative merits of such papers as are deemed worthy.

ARTICLE VII. The Committee on Practical Pharmacy and Dispensing, composed of members actually engaged in the retail drug business, shall be elected by the Section on Practical Pharmacy and Dispensing. It shall arrange in advance the business to come before the Section at the next annual meeting. It shall propose a series of subjects for general discussion, and solicit papers on subjects pertaining to the actual practice of pharmacy in retail stores.

ARTICLE VIII. The Committee on Pharmaceutical Legislation and Education, which shall be elected by the Section on Pharmaceutical Legislation and Education, shall keep a record of, and compile for reference, the enactments of the different States regulating the practice of pharmacy and the sale of medicines. It shall report at each stated meeting of the Association what legislation on pharmaceutical subjects has occurred during the year. It shall arrange the business of the Section in advance of its sessions, propose suitable subjects for discussion, and shall attend to such duties as may be delegated to it by the Section. It shall propose each year a subject for discussion at the meetings of the State Associations, and, at the following annual meeting of this Association, shall present a report of the action of the State Associations upon the subject proposed.

ARTICLE IX. The Committee on Historical Pharmacy shall be elected by the Section on Historical Pharmacy. It shall arrange the business of the Section and shall present annually matters of special historical interest in pharmacy. It shall also secure the collection of letters, papers, etc., written by members of the Association, which when so collected shall remain in the custody of the committee and be available for reference to any one interested.

ARTICLE X. The Committee on the United States Pharmacopoeia shall be appointed by the President of the Association, as follows: One member to be appointed for ten years and one for nine, eight, seven, six, five, four, three, two and one years respectively, each vacancy occurring by expiration of term to be filled by a new appointment for ten years. The Committee shall elect its own Chairman annually. It shall collect statistics regarding the frequency with which official and non-official remedies are used in legitimate practice, and shall endeavor to ascertain the general wishes and requirements of the profession throughout the country in regard to any desired changes or improvements in the Pharmacopoeia. It shall also note errors of any kind found in the U. S. Pharmacopoeia, so as to facilitate and aid the work of the National Committee on Revision of the U. S. P.

ARTICLE XI. The Committee on Transportation, which shall be elected by the Council, shall consist of one member each from the cities of Boston, New York, Chicago, St. Louis, Cincinnati, New Orleans, Atlanta, St. Paul or Minneapolis, Denver and San Francisco, and in conjunction with the General Secretary and the Local Secretary, who shall be members of the Committee, shall arrange for transportation from the different sections of the United States and Canada to the place of meeting and return. The Council shall annually elect the Chairman of this Committee.

ARTICLE XII. The Committee on the Pharmaceutical Syllabus shall be appointed by the President of the Association as follows: One member shall be appointed for seven years, and one for six, five, four, three, two and one years respectively; each vacancy occurring from expiration of term shall be filled for a term of seven years; other vacancies shall be filled at the annual meetings of the Association for the unexpired terms.
This committee shall report to the Association through the Section on Pharmaceutical Legislation and Education, shall be members of the National Committee on the Pharmaceutical Syllabus and shall recommend to the Association its proportionate share of the current expenses.

CHAPTER XI.

Rules of Order and Debate.

ARTICLE I. The ordinary rules of parliamentary bodies shall be enforced by the presiding officer, from whose decision, however, appeals may be taken, if required by two members, and the meeting shall thereupon decide without debate.

ARTICLE II. When a question is regularly before the assembly and under discussion, no motion shall be received but to adjourn, to lay on the table, for the previous question, to postpone to a certain day, to commit or amend, to postpone indefinitely; which several motions have precedence in the order named. A motion to adjourn shall be decided without debate.

ARTICLE III. No member may speak twice on the same subject, except by permission, until every member wishing to speak has spoken.

ARTICLE IV. On the call of any two members, the yeas and nays shall be ordered, when every member shall vote, unless excused by a majority of those present, and the names and manner of voting shall be entered on the minutes.

ARTICLE V. On all points of order not covered in these By-Laws, the Association shall be governed by the established usages in all assemblies governed by parliamentary rules.

CHAPTER XII.

Local Branches.

ARTICLE I. Local branches of this Association may be formed wherever it may appear that twenty-five members of this Association, in good standing, will participate, provided that no more than one such branch shall be formed in any one State, province, district or territory, unless the additional branches shall be formed at a point distant one hundred miles or more from any branch already established in the same State, province, district or territory.

ARTICLE II. All active or voting members of local branches must be members of this Association in good standing.

ARTICLE III. The objects and aims of local branches of this Association shall be the same as set forth in Article I of the Constitution of this body, and the acts of local branches shall in no way commit or bind this Association, and can only serve as recommendations to it. And no local branch shall enact any article of Constitution or By-Law in conflict with the Constitution or By-Laws of this Association.

ARTICLE IV. Each local branch having twenty-five active or voting members shall be entitled to elect one member every three years, who shall become and continue a member of the Council of this Association for that time.

CHAPTER XIII.

Miscellaneous.

ARTICLE I. Every proposition to alter or amend these By-Laws shall be submitted in writing at a general session, and may be balloted for at any subsequent general session, when, upon receiving the votes of three-fourths of the members present, it shall become a part of the By-Laws.
BY-LAWS OF THE COUNCIL.

CHAPTER I.

Article I. The officers of the Council shall consist of a Chairman, a Vice-Chairman and a Secretary, who shall be elected by ballot by the Council, to serve one year.

Article II. They shall be elected and shall assume the duties of their respective offices after the election of the new members of the Council by the Association.

CHAPTER II.

Of the Chairman and Vice-Chairman.

Article I. The Chairman shall preside at all meetings of the Council; in his absence or on account of inability from any cause, the Vice-Chairman, or, in the absence of both, a Chairman pro tempore, shall perform the duties of Chairman.

Article II. The Chairman of the Council shall confer with the Chairmen of the various special and standing committees of the Association, during its sessions, in order to arrange and expedite the business of the Association.

CHAPTER III.

Of the Secretary.

Article I. The Secretary shall keep fair and correct minutes of the proceedings of the meetings, and carefully preserve all reports and papers of every description received by the Council. He shall receive an annual salary not to exceed $300.

Article II. He shall read all the papers handed him by the Chairman for that purpose; shall call and record the yeas and nays whenever they are required to be called; he shall notify the Chairman of every special committee of his appointment, giving him a list of his colleagues, and stating the business upon which the committee is to act, and shall notify every member of the time and place of each meeting of the Council.

Article III. The Secretary of the Council shall also officiate as Secretary of the Committee on Membership.

CHAPTER IV.

Of Committee on Membership.

Article I. The Committee on Membership shall consist of seven members of the Council, to be elected annually by ballot. The General Secretary and the Treasurer of the Association shall be ex-officio members of this committee. The committee shall elect its chairman immediately after the election of its members by the Council.
BY-LAWS OF THE COUNCIL.

ARTICLE II. The Committee on Membership shall be charged with the duty of keeping a correct list of the members of the Association, and shall present to the Council the list of applicants for membership who have complied with the requirements of the By-Laws of the Association.

ARTICLE III. It shall furnish appropriate biographical sketches of deceased members for publication in the Report of the Proceedings.

CHAPTER V.

Of Committee on Publication.

ARTICLE I. The Committee on Publication shall consist of five members, to be elected by ballot by the Council. Immediately after its election by the Council, the Committee shall elect a Chairman.

ARTICLE II. The Committee on Publication shall have charge of the publication and distribution of the Report of the Proceedings.

CHAPTER VI.

Of Committee on Finance.

ARTICLE I. The Committee on Finance shall consist of three members, who shall audit all bills of the Association, and orders on the Treasurer for the payment of bills shall not be issued without the consent of the Finance Committee.

CHAPTER VII.

Of the Centennial Fund.

ARTICLE I. A Committee on the Centennial Fund shall be formed, consisting of the President or one of the Vice-Presidents of the Association, of the Chairman of the Committee on Finance, and of the General Secretary. It shall receive applications in writing from members for grants from the interest derived from the Centennial Fund, the applications to be accompanied by a statement of the investigation to be made, and of the amount and cost of material required—it being understood that the results of the investigation, together with a full report thereon, be laid before the annual meeting of the Association.

ARTICLE II. The Committee shall consider these applications, and at as early a date as possible shall report to the Council an outline of the proposed investigations, together with such recommendations of grants from the available funds as it may deem proper.

ARTICLE III. The Council shall decide upon these recommendations, and in case the grants be approved, the Chairman of the Council shall direct orders to be drawn upon the Treasurer in favor of those members to whom grants have been made.

CHAPTER VIII.

Of Sessions.

ARTICLE I. The Council shall meet previous to the assembling of the Association, and at such other times as it may determine, or at the call of the Chairman.
ARTICLE II. On the written application of three members to the Chairman of the Council, a special session shall be called.

ARTICLE III. Nine members of the Council shall constitute a quorum.

ARTICLE IV. The order of business at the first session of the Council shall be as follows:

1. Organization by the election of the Chairman, Vice-Chairman, and the Secretary.
2. Election of the Standing Committees of Council, as follows:
   a. Committee on Membership, consisting of seven members of the Council, the General Secretary and the Treasurer.
   b. Committee on Finance, three members.
   c. Committee on Publication, five members.
   d. Committee on Centennial Fund, three members.
3. Unfinished and deferred business from the last Council, or such business as is especially referred to the Council from the Association.
4. The reading of the names of new members as provided in the By-Laws.
5. Reading of reports and appointment of committees.
7. Adjournment—and before the final adjournment, the minutes of the last session of the Council shall be read and approved.

CHAPTER IX.

Miscellaneous.

ARTICLE I. Three members of any of the Standing Committees shall constitute a quorum for the transaction of business.

ARTICLE II. In all questions arising before the Council or its Committees, and which can be disposed of by a positive or negative vote, the Chairman of the Council, or the Chairman of the Committee, may take the vote of their respective bodies in writing, and the same shall have the same force and effect as if the members had been personally present, a majority of the votes cast being considered sufficient to decide a question. The ayes and nays of such votes taken by the Council shall be entered upon the minutes.

ARTICLE III. Every proposition to alter or amend these By-Laws shall be submitted in writing, and may be balloted for at the next session of the Council, when upon receiving the vote of three-fourths of the members present, it shall become a part of these By-Laws.
GENERAL RULES OF FINANCE.

ADOPTED 1883, AMENDED 1885, 1887, 1888, 1895, 1900, 1901, 1903, 1909, 1910.

First, The Treasurer shall deposit all moneys received by him, except those belonging to the various “Funds,” with some reliable banking company, where said money may be drawing interest for the benefit of the Association, said banking company to be designated by the Finance Committee and approved by the Council.

Second, Said money shall be deposited in the name of the American Pharmaceutical Association, and all checks shall be drawn by the Treasurer, and shall be countersigned by the Chairman of the Council.

Third, All bills due by the Association shall be paid by numbered checks on said banking company, the checks, when returned to the Treasurer, to be attached to the several vouchers.

All bills for payment shall take the following course: The correctness of the bill shall be certified to by the person contracting the same. After approval by the General Secretary, he shall endorse upon the bill the appropriation against which it is to be charged, and submit it to the chairman of the Finance Committee for his approval. A warrant shall then be drawn and signed by the General Secretary and the President upon receipt of which the Treasurer shall draw a check for the amount.

Fourth, The Treasurer shall make a deposit in the bank whenever the money in his hands shall amount to fifty dollars.

Fifth, The Treasurer shall be the custodian of the bonds and saving-bank books, representing the several Funds belonging to the Association; and bonds and bank-books shall be in the name of the Treasurer, and the accounts of the same shall be kept by him.

Sixth, There shall be annually appointed by the Council an Auditing Committee, this Committee to consist of three members residing in or near the same city or town, as that in which the Treasurer resides, the Chairman to be named by the Chairman of the Council.

Seventh, The Treasurer shall balance his books July 1st of each year, and shall make out, previous to the fifteenth day of July following, his annual report for the financial year just closed.

Eighth, The Treasurer, having thus balanced his books and made out his report, shall place all his books, accounts, vouchers, etc., with the report, at the disposal of the Chairman of the Auditing Committee, at such time and place in July of each year as said Chairman may direct.

The Treasurer, in the presence of another member of the Association, shall make a list of the numbers and amounts of the bonds belonging to the Association, and both shall make affidavit to such list, which shall then be forwarded to the Auditing Committee for their use in auditing the books of the officers of the Association.

Ninth, Said books, accounts, vouchers, saving-bank books and accounts of the same shall be returned to the Treasurer within two weeks of the date of their reception by the Chairman of the Auditing Committee.

Tenth, There shall be a meeting of the Auditing Committee in July of each year, and it shall be the duty of said Committee, at such meeting, to carefully examine all the books, accounts, vouchers, funds, etc., etc., received by them; and previous to the 1st day of August following, to make a report thereon, in writing, to the Chairman of the Council.
Eleventh, The expense of the bond of the Treasurer, given by a Trust Company, shall be paid for from the Treasury.

Twelfth, The Treasurer shall furnish with his annual report an alphabetical list of the names of the members from whom he has received money for dues and certificates during the financial year, for publication in the Proceedings.

Thirteenth, The Finance Committee shall each year, previous to June 1st, present to the Council for its consideration a list of appropriations to cover the various expenditures of the coming fiscal year, the total of such appropriations to be based on the probable amount to be received from the annual dues for the coming year. No payment shall be made in excess of said appropriation except by special vote of the Council. All motions and resolutions involving the expenditure of any sum in excess of twenty-five dollars shall be referred to the Finance Committee before being acted upon by the Council. Provided, however, that the Treasurer shall be authorized to transfer from one account to another, such amount as may be needed at any time, the amount of any such transfer not to exceed the sum of fifty (50) dollars.

Fourteenth, All balances remaining from appropriations at the close of each fiscal year shall be turned back into the treasury, unless otherwise ordered by the Council.

Fifteenth, The Chairman of the Council is instructed to appoint three members of the Association who, together with the Treasurer, shall be known as the Committee on Invested, Savings and Trust Funds.

Of the three members first appointed, one shall be appointed for one year, one for two years and one for three years. Each year thereafter, one member shall be appointed for three years. Members of the committee need not be members of the Council.

It shall be the duty of the said committee to carefully consider the nature and status of all invested, savings and trust funds of the Association, and to make an annual written report upon the same to the Council, which report shall be read (in full) at one of the general sessions of the annual convention of the Association, and published in full in the annual volume of Proceedings thereof.

The present custody of the funds shall not be affected by the adoption of these resolutions, neither shall the committee have the power to invest or re-invest any of such funds, except as instructed by the Council or Association.
GENERAL RULES OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

At the forty-seventh annual meeting of the American Pharmaceutical Association, held at Put-in-Bay, O., Sept. 4-12, 1899, the Council resolved that no advertisements be solicited or accepted for any of the publications or programs issued by or in the name of the Association, and the General Secretary was instructed to inform annually the Local Secretary and the Pharmaceutical Press of the resolution.

At the annual meeting of 1907, held in New York City, it was ordered that the three-year term of members of the Council elected by local branches of the A. Ph. A. shall date from the last annual meeting of the Association held previous to the date of election of the new Council member by a local branch. (See Proc. 1907, p. 25.)

At the fifty-seventh annual meeting, held at Los Angeles, Cal., August, 1909, it was ordered that space be annually set aside in the Proceedings for abstracts of the proceedings of the meetings of the National Association of Boards of Pharmacy and the American Conference of Pharmaceutical Faculties.

It was further ordered that the salary year of the officers of the A. Ph. A. be changed so as to run from July of one year to July of the next year, instead of, as heretofore, from September to September. (See Proc. 1909, p. 452.)

It was also ordered that the names of life members, new style, be designated in the Roll and List of Members by means of heavy or black-faced type. (See Proc. 1909, p. 459.)

At the fifty-eighth annual meeting it was ordered that the Committee on Membership submit all names of applicants for membership to the respective State representative on the committee for approval before sending the application to the secretary of membership for submission to the vote of Council, or if they be sent direct to the secretary of the Committee on Membership they shall be sent by him, first to the State representative, for approval.

It was further ordered that the resignation of a member may be accepted during the first six months of the fiscal year for which his annual dues are payable.
ROLL OF MEMBERS.

HONORARY MEMBERS.

FOREIGN COUNTRIES.

ENGLAND.

GERMANY.
Dr. Edward Schaer, Strassburg, 1877. Dr. Ernst Schmidt, Geh. Regierungsrath, Marburg, 1899.

A.

A brief history of pharmaceutical legislation in Pennsylvania, 1299
the Indiana Pharmaceutical Association, 1300
Massachusetts Board of Pharmacy, 1299
catalogue of illustrations of historical apothecary shops, 1296
condensed history of the Wisconsin Pharmaceutical Association, 1300
list of medicinal plants grown by W. C. Coker of Univ. of N. C. Arboretum, 1299
new method of preserving volatile oils, 1121
vegetable adulterant, 995
practical aspect of standards, 502
Absolute alcohol, preparation, 326
Absorbent cotton, preparation, 128
Abstract of proceedings of the 11th annual meeting of the American Conference of Pharmaceutical Faculties, xxvi
Abstracts from the Squibb laboratory note books, 1178
Acacia, mucilage, novel method of straining, 96
preservation by alcohol, 96
Acetic acid, glacial, commercial quality, 350
precaution in determining the strength by titration, 350
ether, conditions affecting its production and composition, 328
Acetone, identification by conversion into acetylcarnbol, 317
iodometric determination, 350
Acetylene, monochlor- and monobrom-, formation of metallic salts, 249
Acid, acetic, glacial, commercial quality, 350
precaution in determining the strength by titration, 350
arsino-salicilyc, 128
benzoic, preparation from toluol with nitric acid, 357
carbonic, solid, formation of pencils with blotting-paper moulds, 248
cinnamic, preparation and properties, 353
eleteric, production from elaterin by caustic alkali, 355
formic, quantitative determination, 355
and formates, volumetric method of estimation, 355
guaiacolsulphonic, new salts, 336
hydrocyanic, a new sensitive test, 250
detection by means of test papers, 250
hydrofluoric, detection in the presence of fluorides, 234
hypophosphite, confirmation of double formula, 245
lactic, modification of Uffelmans's test, 356
mowrc, 187
nitric, determination by reduction with aluminium mercury, 239
nitrohydrochloric, dilute and strong, a practical suggestion, 240
nucleic, properties, 394
phosphoric, determination in acid solution with alkaline molybdate solution and glue, 245
phosphotungstic, a sensitive reagent for ferrous salts, 206

Acids, citric and tartaric, examination for impurities, 353
cresonomic and toluic, pharmacologic distinctions, 337
hypophosphorous and phosphorous, reducing action on certain metallic salts, 244
juniperic and sabicic constitution, 356
lactic and glycolic, very delicate reactions, 357
Aconitin, high percentage of alkaloid, 194
Active members, alphabetical list of, 1376
roll of, 1335
Address, chairman's, Waldo M. Bowman, 571
Chas. H. LaWall, 605
Otto Raubenheimer, 1089
M. J. Wilbert, 724
of chairman of the Council, F. C. Godbold, 448
welcome, Hon. Wm. H. Manny, 418
D. C. Richardson, 424
on behalf of the P. H. and M. H. Service, 427
president's, H. H. Rusby, 434
Adenium hongkong, a poison plant of the French Sudan, 145
Adjab butter, 188
Adrenalin, a new characteristic reaction, 396
Adrenochrom, 138
Adulterated drugs, frequent occurrence, 149
Adulterated vegetable drugs, 1064
Afermol, 128
African cannabis, inferiority to Indian cannabis, 220
Agaroma, 128
Agarose, 128
Ageratum conyozoides, alkaloidal constituent, 189
mexicanum, alkaloidal constituent, 189
Agfa, 130
Aijowan oil, constituents, 203
Albumen, color reaction, 385
determination in urine, 385
meat extract, 84
modification of Ebsch's method of estimation in urine, 386
simple and reliable method of determination in urine, 386
new two reactions, 386
Alcohol, absolute, preparation, 326
and alcoholic beverages of the U. S. P., 326
amyl, color reaction with a-naphthol, 335
commercial versus U. S. P. alcohol, 958
methyl, question of toxicity, 331
rapid determination, 326
tables of the U. S. Bureau of Standards, new, 327
Alcoholic galenicals, reduction of alcohol, 67
Algerian aurantaceous volatile oils, properties, 295
Alkaline antisepctic solution, bleaching and spontaneous restoration of color, 94
earths, microchemical detection, 256
Alkaloidal salts, indirect determination by titration of the combined acid, 339
Alkaloids and salts, sulphuric acid test, 360
cinchona, and their salts, solubilities in water, 365
new method of distinction, 364
modification of Volhard's method of titration, 339

(1429)
INDEX.

Alkaloids, new reaction with hydrogen dioxide, 360
  nitro-derivatives as precipitants, 360
  opium, degree of representation in the official (Ph. Neerland) opium preparations, 358
  Alkaloidal salts, solubilities, 358
  Alkatan, origination of the coloring matter, 183
  Alkyl iodides, action on mercury-ammonium salts, 374
  Almacein, 128
  Aloe-emodin, constitution, 378
  Aloinose, 370
  Aloin, glucosidal nature, 380
  Aloin, character of the hydrolytic sugar, 379
  Athers, Wm. C., The Pharmacopoeia of the United States, 1223
  Alphabetic list of names of members from whom money has been received by the treasurer for annual dues or certificates, from July 1, 1909, to July 1, 1910, 1305
  Alisol, 368
  Alum, exsiccated, moisture absorbed on exposure, 264
  Sodium, preparation and properties, 264
  Aluminoil, 129
  Aluminium, metallic, rapid method of determination, 263
  Nitride, new process of preparation, 264
  sensitive micro-chemical reactions, 267
  utensils, precautions in using, 53
  Amber, solubility in different solvents, 288
  Amendments to by-laws, adoption of, 464, 465
  proposed, 464, 466, 512, 518
  Ameyl, 129
  American tea, production beyond the experimental stage, 139
  Amydazo-toluol medicinale, 130
  Ammonia liminment, acidity of oils a desideratum, 90
  water, presence and detection of pyridine, 68
  Ammonium benzoate, the pharmacopoeial tests, 352
  nitrate, utility in the analysis of metals, 254
  phosphate, volumetric determination, 254
  Amorphous carbon, decolorizing properties of various kinds, 247
  Ampoule, sublimate, 143
  Ampul filler, efficient, 59
  the, and its uses, 59
  Amygdalin, hydrolysis with acids, 378
  Amyl alcohol, color reaction with a-naphthol, 335
  Amylodextrin, crystallized, 348
  Amylose, crystallized, 348
  Andrographis paniculata, a remedy in kidney-gravel, 180
  Andropogon grasses, cultivation in Ceylon, 160
  Animal charcoal, arsenic a contaminant, 247
  Anisohexobromine, 130
  Antilepros, 130
  Antimonium sulphurat and golden sulphides of antimony, 278
  composition and impurities, 278
  Antimony and potassium tartrate, U. S. P. method of assay, 354
  origin of the name, 278
  Antimonyl aniline tartrate, 139
  Antipyrine, a sensitive reagent, 374
  Apol, crystalline, protest against inclusion in the French Pharmacopoeia, 380
  Apols, commercial, physiological action, 380
  Apocynum androsaemifolium, volatile oil from the rhizome, 185
  Apomorphine, contamination with trimorphine, 369
  hydrochloride, false, 369
  presence of true apomorphine, 370
  Apparatus and manipulation, 34
  extraction, Dunston and Short's modification, 49
  simple form, 49
  Kipp's, new modification, 239
  melting point, simple, 52

Apple, Franklin M., election as chairman of the Section on Commercial Interests, 597
  Is the U. S. P. Standard for Pepsin Satisfactory to the Practical Pharmacist? 1125
  Application for permission to form a branch of the A. h. a. at Nashville, Tenn., 457
  from the N. A. R. D. to use part of the text of the N. F. in an edition of "The Modern Pharmacist," 452
  Argentamine, use as a substitute for silver nitrate in microscopy, 281
  Argon, preparation from the air, 240
  Argonin, 130
  Arnica rhizomes, false, examination, 190
  root oil, constituents, 294
  Army, H. V., Board Examination Questions, 693
  Arsenic and F. H. C. I., Fluidextracts and Recpercolation, 1104
  Arsanilic acid, 131
  Arsenic toluarene tartrate, preparation and properties, 277
  hämatose, 131
  Arsenates, new double preparation, 277
  Arsenic trioxide, electrolytic method of detection in arsenic acid, 277
  Arsotropin, 131
  Artemisia oil, high percentage of l-camphor a constituent, 294
  Artificial coloring matter in galenicals, detection by means of hydrogen dioxide, 383
  Asafetida, powdered, commercial, 101
  Ash standards in drugs—are they necessary? 750
  Asher, Philip, election as associate on Committee on Education and Legislation, 637
  Asparagose and pseudo-asparagose, 163
  Asparagus, new carbohydricates, 163
  oil, yield and characters, 205
  Assay of opium, nux vomica and chininchina by the processes of some of the newer pharmacopoeias, 829
  physiological, report of committee on, 839
  Assayed products, 148
  Astatol, 131
  Asulol, 131
  Aucubin, distribution in the genus aucuba, 381
  Auditing committee, appointment of, 516
  report of, 482
  Autobiography of P. C. Caudius, 1294
  Autolysis, 131
  Auxilium medicis, 132
  Azobenzene and o-oxyazobenzene, production from aniline with caustic potash, 287
  Azolla caroliniana, a mosquito destroyer, 158
  Azomethane, formation and characters, 335
  B.
  Balsam, gurjun, constituents, 200
  myrocarpus, a relic of medieval medicine, 211
  Bananas, dried, composition, 165
  Bark, quillia, false, 210
  quilled, 210
  spurious varieties, 209
  wild cherry, constituents, 209
  isolation and characters of glucosides, 208
  Barks, pomegranate, Japanese, alkaloidal content, 207
  soap, new varieties, 210
  Basic peroxide, formation and properties of some new compounds, 375
  Bassia longiolola, a saponin-digitinin glucoside in the seeds, 182
  Bay oil, low eugenol content from the Fiji Islands, 296
  Beak, Jas. H., election as chairman of the Council, 516
  reply to address of welcome, 426
  Beaker flasks, graduated, 58
  Bebes or California bees, 154
INDEX.

Castor oil, powdered, 107
Cautag, formalin-iodine, preparation, 126
Carbon, amorphous, decolorizing properties of various kinds, 247
composition of the ordinary forms, 246
Carbonic acid, solid, formation of pencils with blotting-paper moulds, 248
Caustic potash, paraffin in commercial sticks, 231
soda, fused, action of metals, 252
Cedar oil, true Lebanon, preparation and characters from authentic wood, 306
Celery oil, constituents, 300
Centennial fund, the, xxiii
Cerates and ointments, suitable base, 121
Ceromomentum, 132
Cethal, 132
Chairman’s address, W. M. Bowman, 571
Eug. G. Eberle, 1268
Chas. H. LaWall, 605
Otto Raubenheimer, 1089
M. I. Wilbert, 734
Chamomile oil, distinct oils in the florets and receptacles, 302
Charcoal, animal, arsenic a contaminant, 247
Chemicals, U. S. P., manufacture and official tests, 227
Cherry-laurel water, reliability of the Ph. Helv. formula, 69
Chicle, character of identity, 188
Chilblain cones, formula, 127
Chinotneth, 132
Chloro-perfoliata, occurrence of gentiopicrin, 185
Chloral, condensation with primary amines, 331
Chloraloses, definite compounds of chloral with sugars, 337
Chlorinated lime, estimation of alkalinity in its solutions, 233
inferiority on the German market, 233
Chlorine, preparation by means of ammonium per sulphate, 233
Chloroform, its purity when prepared from acetone the cause of irregularities in narcosis, 239
Chloroforamin pro narcosi, proposed tests of the G. P., 329
Chlorophyll, comparative examination in different plants, 283
conditions for its formation, 283
reduction by alcalies, 384
Chloroxylen swieteniana, presence of an irritant alkaloid, 200
Choleglycerin, 132
Cholestrin, benzoyl superoxide as reagent, 395
Cholestrol, combination with sapoïnins, 394
Choline, possible errors regarding its presence in animal fluids and tissues, 356
Chromium, sensitive micro-chemical reactions, 267
Chromyl subchloride, formation and properties, 266
Chrysanthemum oil, constituents and constants, 303
Cicer arrietinum, carbohydrates of the seeds, 212
Cimicifuges racemosa, constituents of the rhizome, 105
Cinchona alkaloids and their salts, solubilities in water, 369
new method of distinction, 364
fungoid disease in Java, 102
improved method of assay, 192
Cinnamic acid, preparation and properties, 353
Cinnamom-bark oil, distinction from cassia-bark oil and cinnamaldehyde, 303
Cinnamomum Loureiri, source of cinnamon used in Japan, 171
Mercador, characters of oil, 171
Tamala, characters of volatile oil from the leaves, 172
Cinnamon bark, Seychelles, botanical source and constituents, 175
oils, difference in composition according to source, 303
water, distilled, manipulation, 70
Citric and tartaric acids, examination for impurities, 355
Citronella grass, occurrence in Ceylon, 161
possible effect of altitude on oil content, 162
Citronella oil, distilled in the Malay Peninsula, 304
from German New Guinea, inferior germoil content, 304
Comoros, constants, 304
Java, citral a constituent, 304
possibly a protection against the tsetze fly, 304
Clark, A. H., On the Assay of Belladonna Plaster and Extract of Belladonna, 852
On the Keeping Qualities of Some U. S. P. Volumetric Solutions, 976
Clavin, commercial composition, 394
Closed, bottle draining and drying, 62
Clove flowers, red, constituents, 214
Clove, direct estimation of volatile oil and eugenol, 201
Cobalt, sensitive micro-chemical reactions, 267
Cocaine and its substitutes, differentiation, 362
chloride, precaution when using chloroform water as solvent, 364
Cocke, Ewing K. and C. A. Duncan, Spiritus Aethers Nitrlos, 1265
Codlinger oil, suggestion for storage, 296
Coffee, caffeine content in raw and roasted seed, 193
extraction of caffeine direct from green berries, 194
Corna nuts, sugar content and its determination, 199
Colchicum, assay of corn and seed, 164
historical study, 164
seed, percentage of sugar in commercial samples, 165
Collapsible tubes, label attachment, 62
College Prize fund, the, xxv
Colloidal silver, instability, 281
Colocynth, constituents of the pulp and seeds, 204
microscopical examination of the powder, 204
Color stains, microscopic, removal from the fingers, 385
Coloring matter in galenicals, artificial, detection by means of hydrogen dioxide, 383
of cotton flowers, glucoside nature and description, 384
Coltsfoot, new phytosterol in the flowers, 190
Comain, 132
Commercial apiols, physiological action, 380
emulsions, determination of oil content, 277
versus U. S. P. alcohol, 958
Committee, auditing, v

Motion not to accept resignation of H. P. Hyn-

son from the committee on National

Formulary, 455

relative to the investment of permanent

funds, legacy and other trust funds, 449

that whenever an appropriation is made by

the Council, the secretary of the Coun-

cil shall notify the parties who are to ex-

pect the appropriation, as well as the

chairman of the committee on finance,

460

to accept resignation of H. M. Whelpley

from committee on reimbursement of

Geo. M. Beringer, 456

adopt certain general rules, 457

the recommendations of the com-

mittee on invested, saving and

trust funds, 455

Motion to amend the by-laws so that the Board of

Council shall not notify as voted in the

annual election only the votes of those

members whose dues have been paid for the

current year, 464

appoint a committee on editing rules, 502

appoint a committee to consider the

desirability and practicability of the

publication of the National Formulary

by the U. S. Pharmacopoeial

Convention, 444

appoint a committee to formulate rules

for the creation of a class of members

to be known as sustaining members, 518

appoint T. Ashby Miller chairman of the

committee on arrangements for the

meeting of 1910, 449

appropriate $20.00 additional for ac-

count of miscellaneous expenses, 451

appropriate $20.00 for certificate of

members on parchment, 456

appropriate $50.00 for expenses of the

committee on the U. S. P., 450

appropriate $50.00 to cover expense of

issuing bulletins to members of the

committee on National Formulary,

455

appropriate $25.00 to pay additional

premium on treasurer’s bond, 452

appropriate the sum of $125.00 to cover

traveling expenses of the general sec-

tary and treasurer, 518

approve the appointment of John C.

Wallace and L. F. Kehler as members of

the committee on opium legislation,

452

approve the investment by the treasurer

of $5000.00 current funds in St. Louis

4 per cent, gold bonds at 101½, 452

approve the proposition that the Secre-

tary of Agriculture should have the

right to establish standards when none

are provided in the U. S. P. or N. F.,

638

authorize the treasurer to invest $5000.00

of the current funds in municipal or

state bonds on approval of the com-

mittee on finance and the chairman of

the Council, 449

change the name of the Motter Prize

Fund to College Prize Fund, 512

change the date of the 58th annual

meeting from May 16–20 to May 3

7

consider the various recommendations

made by the committee on U. S. P.,

334

direct the committee on publication to

insert the pictures of Wm. M. Searby

and Philip C. Candius in the Pro-

ceedings for 1910, 463

direct the secretary of the Council to

write Dr. Wiechmann that at present

his request can not be granted, 464

direct the secretary of the Council to

write to the chief of the Copyright

Division, Library of Congress, for

full information regarding interna-

tional copyright laws, 464

citronella, distilled in the Malay Peninsula, 304 from Comoros, constants, 304

German New Guinea, inferior cinnamon content, 304

Java, as a constituent, 304

possibly a protection against the tsetse fly, 304

cod liver, suggestion for storage, 226

cornada, constituents, 309

cumin, constituents, 309

eucalyptus, Australian vs. United States, 310

feciaria, yield and characters, 310

Galliard dill, sophistication with oil of fennel, 309

hyssop, confirmation of constituents, 310

kryptomeria, constituents, 311

lemon grass, production in the Philippines, 312

linale, Cavenee, constituents, 314

limette, West Indian, properties, 315

myrtle, from Cyprus, constants, 315 of an odor from copaiba, composition and constants, 308

artemisia herba-alba, characters and constants, 224

basil from Comoros, constants, 225

bergamot, encouraging development of its production following the earthquake, 296

ingenious adulteration, 297

black mustard, expressed, economic value, 341

camphor, presence of cadinene in high-boiling fractions, 208

cardamom, monograph proposed for the National Formulary, 297

celery seed, yield, characters and constants, 316

chamomile, two distinct oils in the flower, 301

champaca flowers, preparation in the Philippines, 302

cloves, newly discovered constituents, 305

sophistication with camphor oil fractions, 305

hyacynth, preparation and properties, 310

hydratis, yellow, yield and properties, 312

juniper berries, oxygenous constituents, 307

lantana camara, yield and properties, 311

lemon, terpene constituents, 312

linolee seeds, a substitute for oil from the wood, 314

mentha silvestris from Ceylon, properties, 315

monarda didyma, properties as obtained from half-dried flowers, 315

monodora grandiflora, constituents and constants, 315

morinda citrifolia, properties and constituents, 316

peppermint, French, constituents, 319

new adulterant, 319

petit-grain, constants, 319

pimento acris fruits, properties, 320

rhsu cotinus, properties, 320

star anise, new constituents, 293

storax, gross adulteration, 323

turrentine, distinction of that distilled from the oleoresin and from the wood, 308

improved method of examination, 307

wild celery, properties, 324
Osmium, analytical determination of its oxides and chlorides, 285
formation and properties of hexachloro-
osmates, 285
Osidostose, 139
Ostrich fat, uca and characters, 344
Otto of rose, adulterants, 321
1909, characters, 320
Ovaradi ferrum, 139
Oxid, 140
Ozone, luminosity, 228
question of formation of ultra-violet light, 228
Ph.
Phosphorus, allotrophic state, 241
atomic weight, 241
dichloride, a new compound, 244
disulphide, question of existence, 243
Hittorf’s, distinctive difference from red
phosphorus, 241
hydrides, a new solid modification, 242
Phosphotungstic acid, a sensitive reagent for fer-
rus salts, 266
Physochrom, 140
Physiologic standardization of cardiac stimulants
and depressants, 913
Physiological assay, report of committee on, 939
standardization, value and limitation, 147
Physostigmine, an intensely fluorescent derivative, 379
Phytolacca abyssinica, pharmacology, 176
Phytostenins, characters and occurrence in some
fixed oils, 345
Fill finisher, self-adjusting, 65
Pills, tuberkul, 144
Fine-needle oil, influence of method of distillation,
306
Pipepe, hygienic, 37
Plat, 146
Place of meeting, selection of, 493
Plant extracts, preparation in unaltered active con-
dition, 78
powders, determination of mineral impurities, 100
Plants, snake-bite, South African, 180
Plassmato, 140
Plaster, lead, new formula, 76
rubber, Fr. P., 76
Plasters in the Pharmacopoeia, necessity for revi-
sion, 75
medicinal, assay, 75
rubber adhesive, 75
Platinum, atomic weight, 281
black, method of preparation, 282
formation and properties of hexambrero-
lattinates, 283
sulphates, conditions of formation, 283
trioxide, preparation and properties, 283
trivalent, oxidation, 282
Pneumococci, 176
Podophyllum resin, adulteration with aloes, 103
investigation, 103
Polonium, successful production of helium, 261
from heat generated by its salts, 261
Polyascarihides, new crystallizable, production
from starch, 348
Pomegranate berries, Japanese, alkaloidal content,
207
Poppy seed oil, commercial distinctions and char-
acters, 344
Porcelain mortars, special advantage, 56
Porcindin, 141
Potash, caustic, paraffin in commercial sticks, 251
Potassium carbonate, degrees of hydration, 251
chlorate, impurities in, 252
101
Powder of pepsin, compound, formula, 102
discussion, 78
Powers, plant, determination of mineral impuri-
ties, 100
Powdered asafetida, commercial, 101
castor oil, 102
President’s address, H. H. Rusby, 434
Pressure percolation, experimental work in, 1252
lithiated, Flowrs, 1255
Primula officinalis, glucosidal constituents of the
root, 176
Prichard, Benj. E., election as secretary of the
Section on Commercial Interests, 597
Quinine tannates, true and false kinds, 366
Quinoline sulphasalicylate, composition and properties, 375

R.

Rack, mortur, convenient, 56
    test-tube, convenient, 57
universal laboratory, 59

Radio-active substances, comparison of the a-rays
produced by different substances, 683
Radiumogen, 141

Radium emanations, act on upon the elements of the carbon group, 683
conditions facilitating its liberation, 682

Random notes, 1269
Rare earths, bromates of, preparation, 261
magneto-chemical analysis, 260
six new elements, 260

Raubenheimer, Otto, chairman’s address, 1089
    election of secretary of Section
on Historical Pharmacy, 1301

Introduction to a symposium
on the pharmacopoeias of the world, 1135
Methylene Blue in Urine—
Its Detection, 992
U. S. P. and N. F. Limit-
ments compared with
these of the Foreign Phar-
macopoeias, 1226

Reagent, Nessler’s, preparation, 254

Receipts for round labels, 64

Recommendations of the committee on invested,
savings and trust funds, 453
regarding investment of the
Endowment fund, 453

Red clover flowers, constituents, 211

Reply to address of welcome, H. M. Whelpley, 422
Jas H. Beal, 426

Report of auditing committee, 373
chairman of committee on Bulletin, 506
    committee on address of chairman of
Section on Practical Pharmacy and Dis-

cussing, 1223

weights and measures, 504

INDEX.
INDEX.

Report of committee on Wm. Procter, Jr. monument fund, 554 to nominate members of the Committee on Unofficial standards, 451 editor of the Bulletin, 467 general committee on membership, 531 historian, 1893 nominating committee, 448 secretary of the Council, 456 Section on Education and Legislation, 60 special committee on editing rules, 520 the financial accounts in the care of the general secretary, 480 reporter to the public press, 565 treasurer, 470 on the invested funds of the Association, 482 progress of pharmacy, 1002 special, of committee on reorganization, to the Council, 572 on communication from the A. M. Reservoir burette, simple construction, 37 Resin of podophyllum, investigation, 203 Resolution in regard to poison labels under the Food and Drugs Act, 689, 692 relative to patent and trademark laws, 665 Resolutions adopted by the Chicago Academy of Medicine, 705 bearing on the sessions of the various sections, 566 from the Section on Scientific Papers, 547 on drug reform, 462 death of Wm. M. Searby, 450 presented by the committee on the Beringer question, 518 soliciting cooperation of the Government departments in work of committees of the A. Ph. A., 504 suggested by the president’s address, 226 adoption of, 503 Resorcinol, characteristic reaction, 338 Respiration, 184 Review of the Belgian Pharmacopoeia III, 1146 British Pharmacopoeia, 1160 French Codex, 1151 German Pharmacopoeia, 1157 Hungarian Pharmacopoeia, 1167 Japanese Pharmacopoeia, 3rd edition, 1195 Netherlands Pharmacopoeia, 1202 Spanish Pharmacopoeia, VIII, 1211 Revision of cyanide and its oxidation products, 979 the U. S. P., suggested standards and changes, 66 Rhamnus cartholica, adulterant or substitute for frangula bark, 218 purshiana, fluidextract, characters of identity, 86 Rhizoma, aristolchii, Paraguay, 168 Rhodium, gravimetric reduction of its compounds, 284 Rhubarb, source of Chinese sorts, 174 Rhus, nature of the poisonous principle, 216 Rice, facing of, with sail, 159 Indian, composition, 158 Richardson, W. S., report of committee on parcels post, 486 Rimoos salve, 141 Rippe, John R., Laboratory Notes on the Pharmacopoeia, 1058 Robylan, 141 Roll of active members, 1335 honorary members, 1334 Root, gentian, adulteration with rhizome of rumex alpinus, 184 influence of the method of drying on its constituents, 184 jell’s, botanical source and toxicity, 220 kangalugi, a native remedy for African tick, 201 Root licorice, collection in Bokhara, 213 Russian and Sicilian, commercial form and botanical source, 213 Round labels, receptacle for, 54 Rubber adhesive plasters, 75 Rubber plasters, Fr. P. Full, 76 Rubidia and caesia, formation of hydrates, 256 Rubidium and caesium carbonates, degrees of hydration of the neutral salts, 255 Rules, general, of finance, 731 the A. Ph. A., 1333 Rumex ekdonianus, constituents, 175 Rusby, H. E., election as vice-chairman of the Council, 516 president’s address, 434 S. Saalbach, Louis, election as chairman of the Section on Practical Pharmacy and Dispensing, 1352 Saccharin, confirmation of its presence in foods and beverages, 352 Safety syphon, 45 Safron, adulteration with synthetic coloring matter, 166 ground, percentages of moisture and ash, 167 Salicase, an enzyme of salix purpurea, 391 Salol-chloroform, preparation and use in wound treatment, 539 Salossi, 141 Salt, bush-, an African condiment, 253 sea, source of principal supply, 255 Salts, alkaloidal, indirect determination by titration of the combined acid, 359 solubilities, 358 morphine, development of volatile odorous bodies, 370 Samphire oil, prospective source of dill apioi, 321 Sandalwood oil, constants of 200 distillates from Mysore wood, 293 Santyl-Knoll, 141 Sapindus emarginatus, characters and quantity of the saponin in the fruits, 207 Sapo cresolis, B. P. C., modified formula, 104 quinidus glicerinatus, 104 Sartan, 141 Sayre, L. E., Do Pharmacists Properly regard the Official Standards, 1052 Gelsemine and Other Constituents of Gelsemium, 940 Kansas Liquor Laws as They Affect Medicine and Pharmacy, 629 Scammony and its scammony, 1093 Schlettbeck, J. O., appointment as member of the committee on the U. S. P., 521 Schmidt, M. R. and H. Engelhardt, Calcium Sulphide Pulps and Tablets, 1003 Schneider, Albert, Adulteration of Vegetable Drugs, 1064 On Teaching Bacteriology in Colleges of Pharmacy, 697 Resolutions on Drug Reform, 462 Some Objectionable and Unusual Chinese Drugs Imported into the United States, 1066 Scopolamine, influence on the action of morphine, 372 Seeville, Wilbur L., On the Permanence of Alkaloidal Fluidextracts and Tinctures, 874 Some Comments on the Alkaloidal Assay Methods of the U. S. P., 828 Tincture of Cannibates, 1115 Sea salt, source of principal supply, 253 Searby, Wm. M., notice of death of, 450 Secretary of the Council, report of, 459 Seed, mowrah, 187 parsley, unsaponifiable constituents of the fat, 156 watermelon, chemical examination, 205
